4. With ignition switch **ON** and all wiring harness leads connected, connect a voltmeter from the generator Bat terminal-to-ground, from the generator No. 1 terminal-to-ground and from the generator No. 2 terminal-to-ground. A zero reading indicates an open between voltmeter connection and battery.

5. Delcotron alternators have a built in feature which prevents over-charge and accessory damage by preventing the alternator from turning **ON** if there is an open in the wiring harness connected to the No. 2 alternator terminal.

6. If Steps 1 through 5 check out, inspect the alternator as follows. Disconnect negative battery cable. Connect an ammeter or alternator tester in the circuit at the Bat terminal of the alternator. Reconnect negative battery cable.

7. Turn **ON** radio, windshield wipers, lights (high beam) and blower motor on high speed. Connect a carbon pile across the battery (or use alternator tester). Operate engine about 2000 rpm and adjust carbon pile as required, to obtain maximum current output. If ampere output is within 10 amperes of rated output as stamped on generator frame, alternator is not defective. Recheck Steps 1 through 5.

8. If ampere output is not within 10 percent of rated output, determine if test hole is accessible. Ground the field winding by inserting a suitable tool into the test hole. Tab is within $\frac{3}{4}$ inch of casting surface. Do not force suitable tool deeper than an inch into end frame to avoid damaging alternator.

9. Operate engine at moderate speed as required and adjust carbon pile as required to obtain maximum current output.

10. If output is within 10 amperes of rated output, check field winding, diode trio and rectifier bridge. Test regulator with an approved regulator tested.

11. If output is not within 10 amperes of rated output, check the field winding, diode trio, rectifier bridge and stator. If test hole is not accessible, disassemble alternator and repair as required.

OVERCHARGED BATTERY TEST

1. Check the condition of the battery before any testing is done.

2. If an obvious overcharging condition exists, remove the alternator from the vehicle and check the field windings for grounds or shorts. If defective, replace the rotor. Test the regulator.

ALTERNATOR DIAGNOSTIC TESTER (J-26290)

This special diagnostic tester is de-

signed to determine if the alternator should be removed from the vehicle.

1. Install tester J-26290 according to manufacturers instructions.

2. With the engine **OFF** and all lights and accessories **OFF**, test the alternator as follows. Light flashes, go to Step 3. Light **ON**, indicates fault in tester which should be replaced. Light **OFF**, pull plug from generator. A flashing light, indicates the alternator should be removed and the rectifier bridge replaced. Light **OFF**, indicates faulty tester or no voltage to tester. Check for 12 volts at No. 2 terminal of harness connector. Repair wiring or terminals if 12 volts is not available. Replace tester if 12 volts is available.

3. With the engine at fast idle and all accessories and lights **OFF**, test the alternator as follows. Light **OFF** indicates the charging system good, do not remove alternator. Light **ON** indicates a component failure within the alternator. Remove alternator and check diode trio, rectifier bridge and stator. Light flashing indicates a problem within the alternator. Remove alternator and check regulator, rotor field coil, brushes and slip rings.

VOLTAGE REGULATOR TEST (ALTERNATOR ON VEHICLE)

1. Connect a battery charger and a voltmeter to the battery.

2. Turn the ignition switch **ON** and slowly increase the charge rate. The alternator light in the vehicle will dim at the voltage regulator setting. Voltage regulator setting should be 13.5–16.0 volts. This test is performed to determine if the voltage regulator setting is within specifications. This test is accu-

rate even if the stator rectifier bridge
or diode trio is faulty.

VOLTAGE REGULATOR TEST (ALTERNATOR OFF VEHICLE)

1. Remove the alternator from the vehicle.
2. Disassemble the alternator and remove the voltage regulator.
3. Connect a voltmeter and a fast charger to a 12 volt battery. Connect a test light to the regulator and observe the battery polarity.
4. The test light should light.
5. Turn ON the fast charger and slowly increase the charge rate. Observe the voltmeter, the light should go out at the voltage regulator setting. The voltage regulator setting specification is 13.5-16.0 volts.

ALTERNATOR BENCH TEST

1. Remove the alternator from the vehicle. Position the unit in a suitable test stand.

2. Connect the alternator in series, but leave the carbon pile disconnected.

NOTE: Ground polarity of the battery must be the same as the alternator. Be sure to use a fully charged battery and a 10 ohm resistor rated at 6 watts or more between the alternator No. 1 terminal and the battery.

3. Increase the alternator speed slowly and observe the voltage.

4. If the voltage is uncontrolled with speed and increases above 15.5 volts on a 12 volt system or 31 volts on a 24 volt system, test regulator with an approved regulator tester and check field winding. If voltage is below 15.5 volts on a 12 volt system or 31 volts on a 24 volt system, connect the carbon pile.

5. Operate the alternator at moderate speed as required and adjust the carbon pile as required to obtain maximum current output.

6. If output is within 10 amperes of rated output as stamped on alternator frame, alternator is good. If output is not within 10 amperes of rated output, keep battery loaded with carbon pile and ground alternator field.

7. Operate alternator at moderate speed and adjust carbon pile as required to obtain maximum output. If output is within 10 amperes of rated output, test regulator with an approved regulator tester and check field winding.

9. If output is not within 10 amperes of rated output, check the field winding, diode trio, rectifier bridge and stator.

Assembly

1. Press against the outer bearing race to push the bearing in.

2. Press rotor into end frame. Assemble collar, fan, pulley, washer and nut. Torque shaft nut 40-60 ft. lbs.

3. Push slip ring end bearing out from outside toward inside of end frame.

4. Place flat plate over new bearing and press from outside toward inside until bearing is flush with end frame.

5. Use the thin wall tube in the space between the grease cup and the housing to push the bearing in flush with the housing.

6. Assemble brush holder, regulator, resistor, diode trio, rectifier bridge and stator-to-slip ring end frame.

7. Assemble end frames together with through bolts. Remove brush retainer wire.

DOMESTIC STARTING SYSTEMS

Starter Motor Testing

TESTING THE STARTER CIRCUIT

The starter circuit should be divided and tested in 4 separate phases:

1. Cranking voltage check
2. Amperage draw
3. Voltage drop on grounded side
4. Voltage drop on battery side

NOTE: The battery must be in good condition for this test to have significance. To accurately check battery condition, use equipment designed to measure its capacity under a load. Instructions accompanying the equipment should be followed.

Cranking Voltage

Connect voltmeter leads to prods tapped into the battery posts (observe polarity and reverse meter leads if necessary). Remove the high tension wire from the distributor cap and ground it to prevent starting. With electronic ignition, disconnect the control box harness from the distributor. Now, turn the key. Observe both voltmeter reading and cranking speed. The cranking speed should be even and at a satisfactory rate of speed, with a voltmeter reading of at least 9.6 volts for 12 volt systems.

Amperage Draw

The amount of current the starter motor draws is usually (but not always) associated with the mechanical problems involved in cranking the engine. (Mechanical trouble in the engine, frozen or worn starter parts, misaligned starter or starter components, etc.) Because starter motor amperage draw is directly influenced by anything restricting the free turning of the engine or starter, it is important the engine and all components be at operating temperatures.

To measure starter current draw, remove the high tension wire from the center of the distributor cap and ground it. With electronic ignition, disconnect the control box harness from the distributor. A very simple and inexpensive starter current indicator is available at auto stores. This indicator is an induction type gauge and shows,

without disconnecting any wires, starter current draw.

Place the yoke of the meter directly over the insulated starter supply cable (cable must be straight for a minimum of 2 in.). Close the starter switch for about 20 seconds, watch the meter dial and record the average reading. If the indicator swings in the wrong direction, reverse the position of the meter.

The cranking amperage draw can vary from 150-400 amperes, depending on the engine size, engine compression and starter type.

NOTE: When starter specifications are not available, average starter draw amperage can be derived from testing a like starter unit, known to be operating satisfactorily.

More accurate but complex equipment is available from many manufacturers. This equipment consists of a combination voltmeter, ammeter and carbon pile rheostat. When using this equipment, follow the equipment manufacturer's procedures and recommendations.

High amperage and lazy performance would suggest an excessively tight engine, friction in the starter or starter drive, grounded starter field or armature.

Normal amperage and lazy performance suggest high resistance or possibly poor connections somewhere in the starter circuit.

Low amperage and lazy or no performance suggest battery condition poor, bad cables or connections along the line.

Voltage Drop On Grounded Side

With a voltmeter on the 3 volt scale, without disconnecting any wires, connect negative test lead of the voltmeter to a prod secured in the grounded battery post. The positive test lead is connected to a cleaned, bare metal portion of the starter motor housing. Close the starter switch and note the voltmeter reading. If the reading is the same as battery reading, the ground circuit is open somewhere between the battery and the starter. In many cases the reading will be very small. The reading shown will indicate voltage drop (loss) between battery ground post and starter housing. The drop should not exceed 0.2 volts. If the voltage drop is above the specified amount, the next step is to isolate and correct the cause. It can be a bad cable or connection anywhere in the battery-to-starter ground circuit. A check of this type should progress along the various points of possible trouble, between the battery ground post and the starter

motor housing, until the trouble spot has been located.

Voltage Drop On Battery Side

Bad starter cranking may result from poor connections or faulty components of the battery or hot phase of the starter motor circuit. To check this phase of the circuit, without disconnecting any wires, connect a lead of a voltmeter to a prod secured in the hot post of the battery and the other voltmeter lead to the field terminal of the starting motor. The meter should be set to the 16-20 volt scale. Before closing the starter switch, the voltmeter reading will be that of the battery. After closing the starter switch, change the selector on the voltmeter to the 3 volt scale. With a jumper wire between the relay battery terminal and the relay starter switch terminal, crank the engine. If the starting motor cranks the engine, the relay (solenoid) is operating.

While the engine is being cranked, watch the voltmeter. It should not register more than 0.5 volts. If more than this, check each part of the circuit for voltage drop to isolate the trouble, (high resistance).

Without disturbing the voltmeter-to-battery hook-up, move the free voltmeter lead to the battery terminal of the relay (solenoid) and crank the engine. The voltmeter should show no more than 0.1 volts.

If this reading is correct, move the same voltmeter lead to the starting motor terminal of the relay (solenoid).

While the engine is being cranked, the voltmeter should show no more than 0.3 volts. If it does, the trouble lies in the relay.

If the reading is correct, the trouble is in the cable or connections between the relay and the starting motor.

DIAGNOSIS

Starter Won't Start Engine

1. Dead battery.
2. Open starter circuit, such as:
 - a. Broken or loose battery cables
 - b. Inoperative starter motor solenoid
 - c. Broken or loose wire from starter switch-to-solenoid
 - d. Poor solenoid or starter ground
 - e. Faulty starter switch
3. Defective starter internal circuit, such as:
 - a. Dirty or burned commutator
 - b. Stuck, worn or broken brushes
 - c. Open or shorted armature
 - d. Open or grounded fields
4. Starter motor mechanical faults, such as:
 - a. Jammed armature end bearings
 - b. Faulty bearings, allowing armature to rub fields
 - c. Bent shaft
 - d. Broken starter housing
 - e. Faulty starter worm or drive mechanism
 - f. Faulty starter drive or flywheel driven gear

5. Engine hard or impossible to crank such as:

- a. Hydrostatic lock, water in combustion chamber
- b. Crankshaft seizing in bearings
- c. Piston or ring seizing
- d. Bent or broken connecting rod
- e. Seizing of connecting rod bearing
- f. Flywheel jammed or broken

6. Starter spins free, won't engage such as:

- a. Sticking or broken drive mechanism

CHRYSLER CORPORATION

Chrysler Reduction Gear Starter

OVERHAUL

Disassembly and Assembly

1. Support assembly in a soft jawed vise; be careful not to distort or damage the die cast aluminum.
2. Remove the through bolts and the end housing.
3. To disassemble the starter motor, perform the following procedures:
 - a. Carefully pull the armature up and out of the gear housing and the starter frame and field assembly.

Exploded view of the reduction gear starter motor—Chrysler

17 CHARGING AND STARTING DOMESTIC

Cross-sectional view of the reduction gear starter motor - Chrysler

b. Remove the steel and fiber thrust washer.

c. Carefully pull the frame and field assembly up enough to expose the terminal screw and the solder connection of the shunt field at the brush terminal.

d. Place 2 wood blocks between the starter frame and starter gear housing to facilitate removal of the terminal screw.

e. Unsolder the shunt field wire at the brush terminal.

NOTE: The starting motors have the wire of the shunt field coil soldered to the brush terminal. A pair of brushes are connected to this terminal. Another pair of brushes are attached to the series field coils by means of a terminal screw.

4. Support the brush terminal with a finger behind terminal and remove the screw. Unsolder the shunt field coil lead from the brush terminal and housing.

5. The brush holder plate (with terminal contact) and brushes are serviced as an assembly. Clean all old sealer from around plate and housing.

6. Remove the brush holder screw. On the shunt type, unsolder the solenoid winding from the brush terminal.

7. Remove the $1\frac{1}{32}$ in. nut, washer and insulator from solenoid terminal. Remove the brush holder plate with brushes as an assembly and the gear housing ground screw.

8. The solenoid assembly can be removed from the well. Remove the nut, washer and seal from starter battery terminal and the terminal from the plate.

9. Remove the solenoid contact and plunger from solenoid and the coil sleeve. Remove the solenoid return spring, coil retaining washer, retainer and the dust cover from the gear housing.

10. Release the snapping that locates the driven gear on pinion shaft. Release the front retaining ring.

11. Push the pinion shaft rearward and remove the snapping, thrust washers, clutch/pinion and the 2 nylon shift fork actuators.

12. Remove the driven gear and friction washer. Pull the shifting fork forward and remove the moving core.

13. Remove the fork retaining pin and shifting fork assembly. The gear housing with bushings is serviced as an assembly.

14. Brushes that are worn to $\frac{1}{2}$ the length of new brushes or oil soaked, should be replaced.

15. When resoldering the shunt field and solenoid lead, make a strong low resistance connection using a high temperature solder and resin flux; do not use acid or acid core solder. Be careful not to break the shunt field wire units when removing and installing the brushes.

16. Do not immerse the starter clutch unit in a cleaning solvent. The outside of the clutch and pinion must be cleaned with a cloth so the lubricant is not washed from inside the clutch.

17. Rotate the pinion. The pinion gear should rotate smoothly and in 1 direction only. If the starter clutch unit does not function properly or the pinion is worn, chipped or burred, replace the starter clutch unit.

18. Inspect the commutator and the surface contacted by the brushes when the starter is assembled, for flat spots, out of roundness or excessive wear.

19. Reface the commutator, if necessary, removing only a sufficient amount of metal to provide a smooth even surface.

Removing the starter drive gear snapping - reduction gear starter motor - Chrysler

Shift fork and clutch arrangement - reduction gear starter motor - Chrysler

Removing the starter drive gear retaining ring - reduction gear starter motor - Chrysler

Removing the clutch assembly - reduction gear starter motor - Chrysler

20. Using light pressure scrape the commutator grooves with a broken hacksaw blade; do not remove any metal or expand the grooves.

21. To assemble, lubricate the bushings and reverse the disassembly procedures. The shifter fork consists of 2 spring steel plates held together by 2 rivets. Before assembling the starter check the plates for side movement. After lubricating between the plates with a small amount of SAE 10 engine oil they should have about $\frac{1}{16}$ in. side movement to insure proper pinion gear engagement.

Nippondenso/ Mitsubishi Reduction Gear Starter

OVERHAUL

Disassembly and Assembly

1. Position the assembly in a soft jawed vise. Remove the rubber boot from the field coil terminal, the nut from the field coil terminal stud and the field coil terminal from the stud.

Exploded view of the Nippondenso reduction gear starter motor—Chrysler

Exploded view of the Bosch reduction gear starter—Chrysler

2. Remove the through bolts and the splash shield. Remove the end shield screws from the brush plate and the end shield.

3. Slide the brushes from the holders. Pry the retaining springs back for access and remove the brush plate.

4. Slide the armature from the starter housing. Remove the starter housing from the gear housing and the solenoid terminal cover.

5. Remove the solenoid terminal nut/washer, the battery terminal nut/washer and the solenoid terminal assembly from the terminal posts.

6. Remove the solenoid terminal and the battery terminal from the insulator.

7. Remove the solenoid cover screws, the solenoid cover, the seal, the solenoid plunger from the housing and the plunger spring.

8. Remove the gear housing-to-solenoid screws and separate the gear housing from the solenoid housing.

9. Remove the reduction gear and clutch assembly from the gear housing.

10. Remove the reduction gear, pin-

ion gear, retainer and roller assembly from the gear housing.

11. Inspect and clean all parts, as required. Repair or replace defective parts as required. Brushes that are worn less than $\frac{1}{2}$ the length of new brushes or oil soaked should be replaced.

12. To assemble, reverse the disassembly procedures.

Bosch Reduction Starter

OVERHAUL

Disassembly and Assembly

1. Position the assembly in a soft jawed vise. Remove the field terminal nut, the terminal and the washer.

2. Remove the solenoid-to-starter screws. Work the solenoid from the shift fork and remove the solenoid from the starter.

3. Remove the starter end shield bushing cap screws, the starter end shield bushing cap, the end shield bushing and C-washer.

4. Remove the starter end shield bushing washer and seal.

5. Remove the starter through bolts, the starter end shield and the brush plate.

6. Slide the field frame from the starter and over the armature. Remove the armature assembly from the drive end housing.

7. Remove the rubber seal from the drive end housing. Remove the starter drive gear train.

8. Remove the dust plate. Press the stop collar from the snapping. Using snapping pliers, loosen the snapping.

9. Remove the output shaft snapping, the clutch stopring collar and the clutch assembly from the starter.

10. Remove the clutch shift lever bushing, the clutch shift lever and the C-clip retainer.

11. Remove the retaining washer, the sun and the planetary gears from the annulus gear.

12. To assemble, lubricate the necessary parts and reverse the disassembly procedures. Replace all defective components as required.

FORD MOTOR COMPANY

Ford Positive Engagement Starter

OVERHAUL

Disassembly and Assembly

1. Remove the starter from the vehicle. Position the unit in a soft jawed vise.

2. Remove the cover screw, the cover, through bolts, starter drive end housing and the starter drive plunger lever return spring.

3. Remove the pivot pin from the starter gear plunger lever, the lever and the armature. Remove the stopring retainer and the thrust washer from the armature shaft.

4. Remove the stopring from the groove in the armature shaft and discard it. Remove the starter drive gear assembly, the brush end plate and insulator assembly.

5. Remove the brushes from the plastic brush holder and lift out the brush holder. Note the location of the holder in relation to the end terminal.

6. Remove the ground brush screws. Remove the sleeve and the retainer by bending up the edge of the sleeve which is inserted in the rectangular hole of the frame.

7. Using the tool 10044-A or equivalent, remove the pole retaining screws. An arbor press may have to be used in conjunction with the special tool.

8. Cut the positive brush leads from the coil fields as close to the field connection as possible.

9. Check the commutator for run-out. If the commutator is rough, has flat spots or is more than 0.005 in. out of round, reface it.

10. Inspect the armature shaft and

Exploded view of the Ford positive engagement starter—4 inch plunger pole

Exploded view of the Ford positive engagement starter—4½ inch plunger pole

17 CHARGING AND STARTING DOMESTIC

the bearings for scoring and excessive wear; replace it, if necessary. Inspect the starter drive; if the gear teeth are pitted, broken or excessively worn, replace the starter drive.

11. Lubricate the necessary parts and reverse the disassembly procedures.

12. Solder the field coil-to-starter switch terminal posts. Check for continuity and grounds in the assembled coils.

13. Position the ground brushes-to-starter frame and rivet securely.

14. Install the starter motor drive gear assembly onto the armature shaft. Install a new stopring, a new stopring retainer and thrust washer.

15. Install the armature.

16. Position the drive gear plunger lever to the frame and starter drive assembly. Fill the end housing bearing bore a $\frac{1}{4}$ full of grease. Position the drive end housing onto the frame and make sure the return spring engages the lever tang. Install the pivot pin.

17. Install the brush holder, the brushes and the brush springs; make sure the brushes are positioned properly to avoid grounding.

18. Install the brush end plate; be sure the end plate insulator is positioned correctly on the end plate.

19. Install the through bolts and torque to 55–80 inch lbs. (6–9 Nm).

20. Install the starter drive plunger over cover and tighten the screw.

21. Check the starter no-load current draw; it should be 80 amps.

bearing screws. Remove the drive gear housing from the armature shaft.

6. To remove the overrunning clutch from the armature shaft, perform the following procedures:

a. Remove the washer or collar from the armature shaft.

b. Using a $\frac{5}{8}$ in. deep socket, slide it over the shaft and against the retainer. Using the socket as a driving tool, tap it with a hammer to move the retainer of the snapping.

c. Remove the snapping from the groove in the shaft; if the snapping is distorted, replace it.

d. Remove the retainer and the clutch assembly from the armature shaft.

7. If required, the shaft lever and the plunger can be disassembled by removing the roll pin.

8. To replace the starter brushes, remove the brush holder pivot pin which positions the insulated and the ground brushes. Remove the brush spring.

9. Inspect armature commutator, shaft and bushings, overrunning clutch pinion, brushes and springs for discoloration, damage or wear; replace the damaged parts.

10. Check fit of armature shaft in bushing in drive housing. The shaft should fit snugly in the bushing; if it is worn, replace it.

11. Inspect armature commutator. If commutator is rough, it should be re-finished on a lathe. Do not undercut or turn to less than 1.650 in. O.D. Inspect the points where the armature conductors join the commutator bars to make sure they have a good connection. A burned commutator bar is usually evidence of a poor connection.

12. Using a growler and holding hacksaw blade over armature core while armature is rotated, inspect the armature for short circuits. If saw blade vibrates, armature is shorted.

13. Using a test lamp place a lead on the shunt coil terminal and connect the other lead to a ground brush. The test should be made using both ground brushes to insure continuity through the brushes and leads. If the lamp fails to light, the field coil is open and will require replacement.

14. Using a test lamp place a lead on the series coil terminal and the other on the insulated brush. If the lamp fails to light the series coil is open and will require repair or replacement. The test should be made from each insulated brush to check brush and lead continuity.

15. If equipped with a shunt coil separate the series and shunt coil strap terminals during the test. Do not allow the strap terminals to touch case or other ground. Using a test lamp place

a lead on the grounded brush holder and the other lead on either insulated brush. If the lamp lights a grounded series coil is indicated and must be repaired or replaced.

NOTE: If the solenoid has not been removed from the starter, the connector strap terminals must be removed before making the following tests. Complete the tests as fast as possible in order to prevent overheating the solenoid.

16. To check the starter winding, connect an ammeter in series with 12 volt battery and the switch terminal on the solenoid. Connect a voltmeter to the switch terminal and to ground. Connect a carbon pile across battery. Adjust the voltage to 10 volts and note the ammeter reading; it should be 14.5–16.5 amperes.

17. To check both windings, connect as for previous test and ground the solenoid motor terminal. Adjust the voltage to 10V and note the ammeter reading; it should be 41–47 amperes.

18. Current draw readings over specifications indicate shorted turns on a ground in the windings of the solenoid; the solenoid should be replaced. Current draw readings under specifications indicate excessive resistance. No reading indicates an open circuit. Check the connections and replace the solenoid (if necessary). Current readings will decrease as the windings heat up.

19. To assemble, reverse the disassembly procedures. Be sure to replace or repair all defective components as required.

NOTE: When the starter has been disassembled or the solenoid replaced, it is necessary to check the pinion clearance. Pinion clearance must be checked in order to prevent the buttons on the shift lever yoke from rubbing on the clutch collar during engine cranking.

20. To check the pinion clearance, perform the following procedures:

a. Disconnect the motor field coil connector from the solenoid motor terminal and insulate the terminal.

b. Connect the positive 12 volt battery lead to the solenoid switch terminal and the negative lead to the starter frame.

c. Touch a jumper lead momentarily from the solenoid motor terminal to the starter frame; this will shift the pinion into cranking position and remain there until the battery is disconnected.

d. Using a feeler gauge, push the pinion back as far as possible and

15. Using a test lamp place a lead on the series coil terminal and the other on the insulated brush. If the lamp fails to light the series coil is open and will require repair or replacement. The test should be made from each insulated brush to check brush and lead continuity.

16. If equipped with a shunt coil separate the series and shunt coil strap terminals during the test. Do not allow the strap terminals to touch case or other ground. Using a test lamp place a lead on the grounded brush holder and the other lead on either insulated brush. If the lamp lights a grounded series coil is indicated and must be repaired or replaced.

NOTE: If the solenoid has not been removed from the starter, the connector strap terminals must be removed before making the following tests. Complete the tests as fast as possible in order to prevent overheating the solenoid.

17. To check the starter winding, connect an ammeter in series with 12V battery and the switch terminal on the solenoid. Connect a voltmeter to the switch terminal and to ground. Connect a carbon pile across battery. Adjust the voltage to 10V and note the ammeter reading; it should be 14.5–16.5 amperes.

18. To check both windings, connect as for previous test and ground the solenoid motor terminal. Adjust the voltage to 10V and note the ammeter reading; it should be 41–47 amperes.

19. Current draw readings over specifications indicate shorted turns on a ground in the windings of the solenoid; the solenoid should be replaced. Current draw readings under specifications indicate excessive resistance. No reading indicates an open circuit. Check the connections and replace the solenoid (if necessary). Current readings will decrease as the windings heat up.

20. To assemble, reverse the disassembly procedures. Be sure to replace or repair all defective components as required.

NOTE: When the starter has been disassembled or the solenoid replaced, it is necessary to check the pinion clearance. Pinion clearance must be checked in order to prevent the buttons on the shift lever yoke from rubbing on the clutch collar during engine cranking.

21. To check the pinion clearance, perform the following procedures:

a. Disconnect the motor field coil connector from the solenoid motor terminal and insulate the terminal.

b. Connect the positive 12 volt battery lead to the solenoid switch terminal and the negative lead to the starter frame.

c. Touch a jumper lead momentarily from the solenoid motor terminal to the starter frame; this will shift the pinion into cranking position and remain there until the battery is disconnected.

d. Using a feeler gauge, push the pinion back as far as possible and check the clearance; the clearance should be 0.010–0.140 in.

e. Pinion clearance adjustment is not provided on the starter motor. If the clearance does not fall within limits check for improper installation and replace all worn parts.

Delco Permanent Magnet Gear Reduction (PMGR) Starter

OVERHAUL

Disassembly and Assembly

1. Remove the starter from the ve-

hicle. Position the unit in a soft jawed vise.

2. Remove the field coil screw, the field frame through bolts and separate the field frame assembly from the drive gear assembly. Separate the armature and the commutator end frame from the field frame.

3. Remove the solenoid screws and the solenoid from the drive housing.

4. Remove the retaining ring, shift lever shaft and housing through bolts. Separate the drive assembly, drive housing and gear assembly.

5. To remove the overrunning clutch from the armature shaft, perform the following procedures:

a. Remove the washer or collar from the armature shaft.

b. Using a $\frac{5}{8}$ in. deep socket, slide it over the shaft and against the retainer. Use the socket as a driving tool, tap the socket with a hammer to move the retainer off of the snapping.

c. Remove the snapping from the groove in the shaft; if the snapping is distorted, replace it.

d. Remove the retainer and the clutch assembly from the armature shaft.

6. To replace the starter brushes, remove the brush holder pivot pin which positions the insulated and the ground brushes. Remove the brush spring.

7. Inspect armature commutator, shaft and bushings, overrunning clutch pinion, brushes and springs for discoloration, damage or wear; replace the damaged parts (if necessary). Check the armature shaft fit in drive housing bushing; the shaft should fit snugly in the bushing. If the bushing is worn, it should be replaced.

8. Inspect armature commutator. If commutator is rough, it should be re-

finished on a lathe; do not undercut or turn to less than 1.650 in. O.D. Inspect the points where the armature conductors join the commutator bars to make sure they have a good connection. A burned commutator is usually evidence of a poor connection.

9. Using a growler and holding hacksaw blade over armature core while armature is rotated, check the armature for short circuits; if the saw blade vibrates, the armature is shorted.

10. Using a test lamp, place a lead on the shunt coil terminal and the other lead to a ground brush. The test should be made from both ground brushes to insure continuity through both brushes and leads. If the lamp fails to light, the field coil is open and will require replacement.

11. Using a test lamp, place a lead on the series coil terminal and the other lead on the insulated brush. If the lamp fails to light, the series coil is open and will require repair or replacement. The test should be made from each insulated brush to check brush and lead continuity.

12. If equipped with a shunt coil, separate the series and shunt coil strap terminals during this test; do not allow the strap terminals to touch the case or other ground. Using a test lamp, place a lead on the grounded brush holder and the other lead on either insulated brush. If the lamp lights, a grounded series coil is indicated and must be repaired or replaced.

NOTE: If the solenoid has not been removed from the starter, the connector strap terminals must be removed before making the following tests. Complete the tests as fast as possible in order to prevent overheating the solenoid.

- 36. Welded connections
- 37. Pinion stop

Cross-sectional view of the Permanent Magnet Gear Reduction (PMGR) starter

17 CHARGING AND STARTING DOMESTIC

13. To check the starter winding, connect an ammeter in series with a 12 volt battery, the switch terminal and to ground. Connect a carbon pile across the battery. Adjust the voltage to 10 volts and note the ammeter reading; it should be 14.5–16.5 amperes.

14. To check both windings, connect as for previous test. Ground the solenoid motor terminal, adjust the voltage to 10 volts and note the ammeter reading; it should be 41–47 amperes.

15. Current draw readings above specifications indicate shorted turns or a ground in the windings of the solenoid; the solenoid should be replaced. Current draw readings under specifications indicate excessive resistance. No reading indicates an open circuit. Check the connections and replace solenoid (if necessary). Current readings will decrease as windings heat up.

16. The roller bearing in the drive housing and the roller bearings in the gear housing must be replaced (if they are dry); do not lubricate or reuse the bearings.

17. To replace the gear housing bearing, use a tube or solid cylinder that just fits inside the housing to push bearing toward the armature side. In the opposite direction, use the tube or cylinder to press bearing flush with housing.

18. To replace the gear housing driveshaft bearing, use a tube or collar that just fits inside the housing and press bearing out; press against the open end of bearing. To install a new bearing, press against the closed end, using a thin wall tube or collar that fits in space between bearing and housing.

Do not press against the flat end of the bearing; this will bend the thin metal of the bearing. As required, replace the drive housing bearing.

19. To assemble, reverse the disassembly procedures. Be sure to replace or repair all defective components as required.

NOTE: When the starter has been disassembled or the solenoid replaced, it is necessary to check the pinion clearance. The pinion clearance must be checked in order to prevent the buttons on the shift lever yoke from rubbing on the clutch collar during engine cranking.

20. To check the pinion clearance, perform the following procedures:

a. Disconnect the motor field coil connector from the solenoid motor terminal and insulate the terminal.

b. Connect the positive (+) 12 volt battery lead to the solenoid switch terminal and the other to the starter frame.

c. Touch a jumper lead momentarily from the solenoid motor terminal to the starter frame; this will shift the pinion into cranking position and retain it until the battery is disconnected.

d. Using a feeler gauge, push the pinion back as far as possible, to take up any movement, and check the clearance; the clearance should be 0.010–0.140 in.

e. Means for adjusting pinion clearance is not provided on the starter motor. If the clearance does not fall within limits, check for im-

proper installation and replace worn parts.

JEEP

Bosch Reduction Gear Starter

OVERHAUL

Disassembly

NOTE: When performing disassembly procedures, do not stike the thin wall stator frame with a hammer or any other instrument. Do not clamp the thin wall stator frame in the jaws of a vise. This may result in damage to the permanent magnets and the stator housing. The starter may be clamped by the mounting flange only.

1. Position the starter motor assembly in a suitable holding fixture, ensuring that it is secured by the mounting flange only. Remove the field terminal nut. Remove the field coil wire (Terminal 45) from the solenoid switch terminal post. Remove the field washer.

2. Remove the solenoid switch mounting screws. Disengage the solenoid switch from the fork lever and withdraw the solenoid switch with the

24. Hexagon screw
25. Screw
26. Coverplate

Exploded view of the Bosch starter—Jeep

armature and return spring from the housing.

3. Loosen the closure cap screws, but do not remove them.

4. Remove the stator frame-to-shield housing hexagon screws, the stator frame with the cover plate, armature and commutator end shield.

5. Remove the cover plate from the surface of the drive end bearing ring gear. Carefully press the armature with the commutator end shield out of the stator frame. At the same time, push out terminal 45 with the sealing rubber.

6. Remove the closure cap screws and remove the closure cap from the commutator end shield. Remove the retaining washer and shims from the armature shaft and remove the commutator end shield.

7. Using the proper tool, remove the brush plate from the armature shaft.

8. Remove the sealing rubber from the bearing pedestal. Remove the planetary gear system with the overrunning clutch and fork assembly from the drive end shield. Mount both assem-

Removing the overrunning clutch and planetary gear system—Bosch starter—Jeep

Removing the armature—Bosch starter—Jeep

blies onto a suitable mounting base in the vehicle position.

9. Using the proper tool, drive the stop ring down the input shaft.

10. With snapping pliers, separate the ends of the retainer far enough to allow removal from the driveshaft without damage. If necessary, carefully remove any burrs or nicks from the driveshaft, otherwise damage to the drive bushing may occur.

Inspection

1. The armature windings, overrunning clutch, and relay must be cleaned with compressed air and a clean dry rag. Other parts, such as screws and the armature shaft may be cleaned with cleaning solvent. Inspect all parts, seals, bushings, and gaskets for wear and damage. Replace all worn parts as required.

2. Inspect the stator frame and permanent magnets for damage. Do not remove the magnets from the stator frame. If the stator frame or magnets are damaged, then replace the stator frame.

17 CHARGING AND STARTING DOMESTIC

3. Loosen and remove the retainer from the planetary gear drive. Remove the ring gear from the driveshaft. Inspect the ring gear for cracks and wear. Check the bushings in the ring gear for excessive play, out of roundness and wear by moving the driveshaft from side-to-side. Check the driveshaft bushing in the drive end shield and commutator end shield with the proper tool. Inspect the driveshaft in the ring gear for wear or damage. Replace the shaft and ring gear, if worn.

4. Inspect the fork lever and bearing pedestal for damage, replace if necessary. Inspect the bearing bushing in the overrunning clutch for wear. Replace the overrunning clutch, if the bearing bushing is worn.

5. Remove and inspect the carbon brushes for excessive wear. The length of a new brush is $1\frac{1}{16}$ in.. If the existing brushes are worn more than $\frac{1}{2}$ the length of a new brush or they are oil soaked, replace the existing brushes.

6. Place the drive unit on the armature shaft and support the armature by hand. Grasp the armature and rotate the drive pinion. The drive pinion should rotate smoothly in 1 direction only. Some resistance may be encountered when rotating the drive pinion; however, as long as the rotation is smooth then the drive unit is in good operating condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred, then replace the unit.

ARMATURE GROUND TEST

1. Position the armature in the growler jaws and turn the power switch to-TEST position.

2. Touch a test probe-to-armature core (1). Touch the other test probe-to-commutator bar (2), 1 at a time and observe the test lamp. The test lamp should not light. If the test lamp lights on any bar, the armature has a short circuit-to-ground and must be replaced.

Performing the armature ground test

Performing the armature short test

Performing the armature balance test

ARMATURE SHORT TEST

NOTE: Never operate the growler with the power switch in the Test position without the armature in the growler jaws.

1. Place the armature in the growler jaws and turn the power switch to the growler position.

2. Hold the steel blade parallel to and touching, the armature core (3). Slowly, rotate the armature 1 or more revolutions in the growler jaws. If the steel blade vibrates at any 1 area of the core, the windings have a short circuit and the armature must be replaced.

ARMATURE BALANCE TEST

1. Place the armature in the growler jaws and turn the power switch to the growler position.

2. Place the contact fingers of the meter test probe (4) across adjacent commutator bars at the side of the commutator.

3. Adjust the voltage control until the pointer indicates the highest voltage on the scale.

4. Test each commutator bar until all bars have been tested; 0 volts across any pair indicates a short circuit and requires the armature be replaced.

ARMATURE RUNOUT TEST

Check that the armature runout is within the range shown on the specifications chart. If the runout is not

within tolerance, then replace the armature.

Assembly

1. Place a light film of 20W SAE oil onto the surface of the overrunning clutch pinion bearing surface.

2. Lightly grease the planetary gear spiral spline with Lubriplate grease.

3. Slide the overrunning clutch with the fork lever and bearing pedestal onto the driveshaft.

4. Slide the stop ring onto the armature shaft

NOTE: When installing the retainer, be careful not to scratch the armature shaft.

5. With snapping pliers, separate the ends of the retainer and carefully install onto the groove in the armature shaft.

6. Using the proper tool, seat the stop ring.

7. The planetary gear bearing is located forward of the planetary gears. Lubricate this bearing thoroughly, but lightly, with 20W SAE oil.

8. Insert the planetary gear train with the the pinion, overrunning clutch, fork lever, and bearing pedestal into the drive housing.

9. Install the rubber seal onto the pedestal bearing.

10. Position and install the cover plate on the surface of the ring gear, ensuring the recess in the cover plate mates with the lug machined in the surface of the ring gear.

11. Using the proper tool, position the brush plate onto the end of the commutator shaft. Slide the brush

Assembling the overrunning clutch and planetary gear system

Seating the stop ring

plate over the commutator, ensuring the brush holders are properly seated in the anchor point. After they are properly seated, remove the tool.

12. Place a light coat of 20W SAE oil onto the felt ring gasket and install the gasket on the commutator end of the armature shaft.

13. Place a light coat of Lithium-based lubricant onto the commutator end shield bushing and install the bushing onto the armature shaft.

14. Slide the commutator end shield onto the armature shaft.

15. Set the armature endplay by installing a shim and the retaining washer. After installing the shim, check the endplay with the appropriate feeler gauges. The endplay should be within the range of 0.002–0.016 in. Should additional shims be required, 3 sizes are available: 0.004 in., 0.047 in. and 0.055 in..

16. After setting the armature endplay, place a light coat of lubricant onto the retaining washer.

17. Position the seal ring against the commutator end shield and place the closure cap into installation position.

18. Install the closure cap screws far enough to hold the closure cap into place, but do not tighten at this time.

19. Support the stator frame by hand and slide the armature with the brush plate and commutator end shield carefully into the stator frame, ensuring that a sufficient gap is left to allow installation of the rubber seal.

20. Install the rubber seal onto terminal 45 and slide the rubber seal into the groove of the stator frame.

21. With moderate force, rotate the pinion gear until the armature spline meshes evenly with the planetary gears.

NOTE: When positioning the stator frame ensure the groove in the stator frame is aligned with and fits into the sealing rubber of the bearing pedestal.

22. Rotate the commutator end shield until the groove on the commutator end shield is aligned with the sealing rubber on the bearing pedestal.

23. When the proper alignment is achieved, install the stator frame-to-drive shield screws and torque to 2.0–2.6 ft. lbs.

24. Torque the closure cap screws to 1.0–1.5 ft. lbs..

25. Engage the solenoid switch armature with the fork lever and insert the armature return spring.

26. Install and tighten the solenoid switch housing screws.

27. Install the field washer and terminal wire (Terminal 45) onto the field terminal post. Install the field terminal nut.

Motorcraft Positive Engagement Starter Motor

The Motorcraft starting system, that is used with all Jeep 6 and 8 cylinder engines, consists of a lightweight positive engagement starter motor, a starter motor solenoid, an ignition/start switch, circuits protected by fusible links and the battery. Vehicles equipped with an automatic transmission also have a neutral safety switch to prevent operation of the starter if the selector lever is not in the **N** or **P** position. The Motorcraft starter motor has a moveable pole shoe and appropriate linkage to engage the drive mechanism. Inside the drive assembly, an overrunning clutch prevents the starter motor from being driven by the ring gear.

OVERHAUL

Disassembly

1. Remove the cover screw, cover, and through bolts.

2. Withdraw the pivot pin that retains the starter gear plunger lever. Remove the plunger lever, starter drive end housing and lever return spring.

3. Remove the stop ring retainer. Remove and discard the starter drive gear-to-armature shaft stop ring. Remove the starter drive gear assembly.

4. Remove the brush end plate and insulator assembly.

5. Remove the brushes from the plastic brush holder and lift out the brush holder. Note location of brush holder with respect to the end terminal.

6. Remove the ground brushes-to-frame screws or rivets.

7. Locate the field coil that operates the starter drive gear actuating lever. Bend the edges on the retaining sleeve of this field coil and remove the sleeve and retainer.

8. Position the starter frame in an arbor press and remove the coil screws. Cut the field coil connection at the switch post lead and remove the small diameter ground wire from the upper tab riveted to the frame. Remove the pole shoes and the coils from the frame.

9. Cut the positive brush leads from the the field coils as close to the field connection point as possible.

Inspection

1. Use a clean dry rag or compressed air to clean the field coils, armature, commutator, armature shaft, brush end plate and drive end housing.

Wash all other parts in solvent and dry with a clean rag.

2. Inspect the armature windings for broken or burned insulation and unsoldered or open connections.

3. Check the plastic brush holder for cracks or broken mounting pads. Replace the brushes if worn to $\frac{1}{4}$ in. in length or if oil soaked.

4. Inspect the armature shaft and bushings for excessive wear and scoring. If necessary, lightly polish damaged surfaces.

5. Examine the wear pattern on the starter drive teeth. To eliminate premature starter and ring gear failure, the pinion teeth must penetrate to a depth greater than $\frac{1}{2}$ the ring gear tooth depth.

6. Examine the starter drive gear for milled, pitted or broken teeth. Replace the starter drive if necessary.

7. Inspect the overrunning clutch by grasping and rotating the pinion gear. The pinion gear should rotate smoothly and freely in the clockwise direction and lock in the counterclockwise direction. Replace if necessary.

HOLD-IN COIL WINDING

RESISTANCE TEST

1. Insert a piece of paper (1) between the contact points to insulate them.

2. With an ohmmeter, measure the resistance between the **S** terminal (2) and the starter motor frame. This will

Performing the hold-in coil winding resistance test

Performing the solenoid contact point connection test

17 CHARGING AND STARTING DOMESTIC

Exploded view of the Motorcraft positive engagement starter motor—Jeep

determine the resistance of the hold-in coil winding.

3. The resistance should be within the range of 2.0–3.5 ohms. If the resistance is not within this range, replace the field winding assembly.

SOLENOID CONTACT POINT CONNECTION TEST

1. With an ohmmeter, measure the resistance through solder joint (3). This will determine the integrity of the solder joint at the contacts.

2. A resistance reading greater than 0 ohms indicates the joint is faulty and must be repaired. If repair is required, resolder the joint.

INSULATED BRUSH CONNECTION TEST

1. With an ohmmeter, measure the

resistance through the solder joint by touching the test probes to the brush and to the copper test bar. This will determine the integrity of the solder joint between the the insulated brush braided wire and the field windings.

2. A resistance reading greater than 0 ohms indicates the joint is faulty and must be repaired. If repair is required, resolder the joint.

FIELD WINDING TERMINAL TO BRUSH CONTINUITY TEST

1. Insert a piece of paper between the contact points to insulate them.

2. Touch the test probes to the field winding terminal and to the insulated brush. This will determine the integrity of all the field winding solder joints.

3. A resistance reading greater than 0 ohms indicates that 1 or more of the

field winding solder joints is faulty. Test each solder joint to identify the faulty joint(s). If repair is required, resolder the joint(s).

TERMINAL BRACKET INSULATION TEST

1. With an ohmmeter, measure the resistance between the bracket and the cap. This will determine if the terminal bracket is properly insulated from the end cap.

2. If the resistance is less than infinite, then the end cap is faulty and must be replaced.

ARMATURE GROUND TEST

1. Position the armature in the growler jaws and turn the power switch to the test position.

2. Touch a test probe-to-armature

Performing the insulated brush connection test

Performing the field winding terminal-to-brush continuity test

Performing the terminal bracket insulation test

core and the other test probe to each commutator bar, 1 at a time and observe the test lamp. The test lamp should not light. If the test lamp lights on any bar, the armature has a short circuit to ground and must be replaced.

ARMATURE SHORT TEST

NOTE: Never operate the growler with the power switch in the test position without the armature in the growler jaws.

1. Place the armature in the growler jaws and turn the power switch to the growler position.

2. Hold the steel blade parallel to, and touching, the armature core (3). Slowly, rotate the armature 1 or more revolutions in the growler jaws. If the steel blade vibrates at any 1 area of the

Performing the armature ground test

Performing the armature short test

Performing the armature balance test

core, the windings have a short circuit and the armature must be replaced.

ARMATURE BALANCE TEST

1. Place the armature in the growler jaws and turn the power switch to the growler position.

2. Place the contact fingers of the meter test probe (4) across adjacent commutator bars at the side of the commutator.

3. Adjust the voltage control until the pointer indicates the highest voltage on the scale.

4. Test each commutator bar until all bars have been tested; 0 volts across any pair indicates a short circuit and requires the armature be replaced.

ARMATURE RUNOUT TEST

1. Lightly polish the commutator

Performing the commutator runout check

with commutator cloth prior to measuring runout. Do not use emory cloth.

2. Measure the commutator runout. If the commutator is greater than 0.005 in. out-of-round or has insulation protruding from between the bars, turn it down on a lathe.

Assembly

1. Position 3 coils and pole pieces into the stator frame interior and support by hand. Install the pole piece screws.

2. Tighten the pole piece screws evenly and at regular intervals, tap the frame lightly with a soft-faced mallet. This will facilitate the alignment of the screws and the pole pieces.

3. Repeat procedures until the screws are securely fastened and the pole pieces are in proper alignment.

4. Install the remaining coil and retainer and bend the tabs to secure the coils to the frame.

5. Solder the field coils and solenoid wire to the starter terminal.

6. Check for continuity and grounds in the assembled coils.

7. Ground the coil, that is located in the area of the retaining sleeve, by positioning the small diameter wire leading from the coil under the copper tab, held by the rivet attaching the contact to the frame.

8. Attach the ground brushes to the starter frame with the screws or rivets.

9. Apply a thin coating of Lubriplate or equivalent, to the armature shaft splines. Install the starter motor drive gear assembly to the armature shaft and install a new retaining stop ring. Install a new stop retainer.

10. Install the armature assembly into the starter frame.

11. Fill the drive end housing bearing bore $\frac{1}{4}$ in. with lubricant. Position the starter drive gear plunger lever to the frame and starter drive assembly.

12. Position the starter drive plunger lever return spring and the drive end housing to the frame.

13. Install the brush holder and insert the brushes and springs into their

17 CHARGING AND STARTING DOMESTIC

respective positions. Position and install the brush holder insulator.

NOTE: When installing the endplate, do not to pinch or crimp the brush leads.

14. Position the end plate to the frame ensuring the plate locator is aligned with the frame slot. Install the thru-bolts and torque them to 55-75 inch lbs.. Install the pivot pin.

15. Thoroughly clean the sealing surface of the lever cover to remove any traces of existing gasket material. Apply rubber gasket compound or equivalent, to the sealing surface of the lever cover. Position the lever cover on the frame and secure with the attaching screw.

16. Check the starter no-load current draw.

Mitsubishi Reduction Gear Starter

OVERHAUL

Disassembly and Assembly

NOTE: Do not place the stator frame in a vise or strike it with a hammer for damage to the permanent magnets could occur.

1. Disconnect the coil wire from the solenoid.

2. Remove the solenoid-to-front end frame screws and the solenoid.

3. Loosen, do not remove the commutator shield-to-brush holder screws.

4. Remove the through bolts, the rubber retainer (under solenoid) and the coin washer.

NOTE: When removing the output shaft assembly, do not loose the armature shaft ball.

5. Remove the stator frame, the commutator shield and output shaft assembly as a unit. Separate the clutch fork from the output shaft assembly.

6. From the stator frame, pull the output shaft assembly forward, then, push the armature and commutator shield to the rearward.

7. Remove the commutator shield-to-brush holder plate screws and the shield; do not remove the brush holder assembly.

8. Using a 22mm socket, slide it up against the commutator, slide the brush holder assembly onto the socket and position the socket/brush holder assembly aside.

9. To disassemble the output shaft assembly, perform the following procedures:

a. Remove the rubber packing ring and the gears.

b. Using a 17mm socket, position it into the armature end of the drive-

shaft and position the assembly in the vertical position, resting on the socket.

c. Using a 12 point 14mm socket, position it against the stopring (on the clutch end). Using a hammer, strike the socket to unseat the stopring and expose the snapping.

d. Remove the socket, the snapping and the stopring from the driveshaft.

e. Using fine sandpaper, remove any burrs from the driveshaft. Remove the overrunning clutch.

10. Using compressed air or dry cloths, clean the armature, the stator frame, the overrunning clutch, the solenoid and the brush holder. Using mineral spirits, clean all other components.

11. Inspect the following parts for damage and replace, if necessary:

a. The stator frame and permanent magnets

b. The driveshaft bushing (armature side)

c. The planetary gear set and driveshaft

d. The starter motor bushing and bearing

e. The carbon brushes for cracks, distortion and wear below 0.354 in.

NOTE: When inspecting the brushes, do not remove the socket from the brush holder.

- | | | | | |

| | 9. Solenoid | | | 22. End cover |

Exploded view of the Mitsubishi reduction gear starter—Jeep

12. Using a growler and a hacksaw blade (placed on top of the armature), rotate the armature and check it for a shorted condition. If the hacksaw blade vibrates, a short exists; replace the armature.

13. Using a test light, place a lead on the armature's core and the other on each commutator segment, inspect the armature for a grounded condition. If a ground exists, the test light will turn ON; replace the armature.

14. Using a test light, place the leads on the adjacent commutator segments. If the test light turns ON between any 2 segments, the armature is shorted and must be replaced.

15. Inspect the commutator out-of-round, if it is more than 0.001 in., re-face it on a lathe.

16. Using motor oil, lubricate the driveshaft and the overrunning clutch bushing. Using Lubriplate®, lubricate the overrunning clutch spiral cut splines.

17. Install the overrunning clutch on the driveshaft/planetary gear assembly, followed by the stopring and the snapping; sure to seat the snapping in the shaft groove and crimp the it with a pair of pliers.

18. Using a battery terminal puller, attach it to the driveshaft tip and press the stopring over the snapping.

NOTE: When installing the stopring, be careful not to scratch the driveshaft.

19. Install the clutch fork, with the assembled planetary gear set, lubricated with lithium grease, into the front end housing; make sure the locating lugs are properly seated in the front end housing.

20. Install the coin washer and the rubber fork retainer.

21. Install the rubber backing ring by placing the largest rubber lug at the top.

22. Install the brush holder onto the armature's commutator; make sure the brushes and brush holders are seated in the holder. Inspect the flex washer and install the commutator shield onto the armature. Install the brush holder screws but do not tighten them.

23. Install the armature assembly into the stator frame and seat the wire grommet into the frame.

24. Be sure the armature spline gear is seated in the planetary gear seat with the armature shaft ball in place. Seat the armature shaft in the shaft bushing bore; rotate the stator frame to align the tabs on the drive housing frame.

25. Install the through bolts and torque to 28 inch lbs. Torque the brush holder screws to 18 inch lbs.

26. To complete the assembly, reverse the disassembly procedures.

IMPORT CHARGING SYSTEMS

Test Instruments

OHMMETER

An ohmmeter is used to measure electrical resistance in a unit or circuit. The ohmmeter has a self-contained power supply. In use, it is connected across (or in parallel with) the terminals of the unit being tested.

AMMETER

An ammeter is used to measure current (amount of electricity) flowing through a unit or circuit. Ammeters are always connected in the line (in series) with the unit or circuit being tested.

VOLTMETER

A voltmeter is used to measure voltage (electrical pressure) pushing the current through a unit or circuit. The meter is connected across the terminals of the unit being tested.

Alternator Testing

Diagnosis

The first step in diagnosing troubles of the charging system, is to identify the source of failure. Does the fault lie in the alternator or the regulator. The next move depends upon preference or necessity; either repair or replace the offending unit.

Alternator output is controlled by the amount of current supplied to the field circuit of the system.

The alternator is capable of produc-

Basic electrical circuits

Ammeter connected to test wire — circuit equipped with external voltage regulator

Voltmeter connected in parallel circuit — circuit equipped with external voltage regulator

Ohmmeter connected to test wire resistance — circuit equipped with external voltage regulator

ing substantial current at idle speed. Higher maximum output is also a possibility. This presents a potential danger when testing. As a precaution, a field rheostat should be used in the field circuit when making the following isolation test. The field rheostat permits positive control of the amount of current allowed to pass through the field circuit during the isolation test. Unregulated alternator capacity could ruin the unit.

NOTE: Most manufacturers of precision gauges offer special test connectors, in sets, that will adapt to the leads and connections of any charging system.

There are certain precautionary measures that apply to alternator tests in general. These items are listed

17 CHARGING AND STARTING IMPORT

in detail to avoid repetition when testing each make of alternator and to encourage a habit of good test procedure.

1. Check alternator drive belt for condition and tension.

2. Disconnect battery cables, check physical, chemical and electrical condition of battery.

3. Be absolutely sure of polarity before connecting any battery in the circuit. Reversed polarity will ruin the diodes.

4. Never use a battery charger to start the engine.

5. Disconnect both battery cables when making a battery recharge hook-up.

6. Be sure of polarity connections when using a booster battery for starting.

7. Never ground the alternator output or battery terminal.

8. Never ground the field circuit between alternator and regulator.

9. Never run any alternator on an open circuit with the field energized.

10. Never try to polarize an alternator, unless directed by the manufacturer of the alternator.

11. Do not attempt to motor an alternator.

12. The regulator cover must be in place when taking voltage limiter readings.

13. The ignition switch must be in the **OFF** position when removing or installing the regulator cover.

14. Use insulated tools only to make adjustments to the regulator.

15. When making engine idle speed adjustments, always consider potential load factors that influence engine rpm. To compensate for electrical load, turn **ON** the lights, radio, heater, air conditioner, etc.

Diagnosis of Charging System

LOW OR NO CHARGING

1. Blown fuse.
2. Broken or loose fan belt.
3. Voltage regulator not working.
4. Brushes sticking.
5. Slipring dirty.
6. Open circuit.
7. Bad wiring connections.
8. Bad diode rectifier.
9. High resistance in charging circuit.
10. Voltage regulator needs adjusting.
11. Grounded stator.
12. Open rectifiers (check all 3 phases).
13. If rectifiers are found blown or open, check capacitor.

NOISY UNIT

1. Damaged rotor bearings.
2. Poor alignment of unit.
3. Broken or loose belt.

Checking the current output of the charging system

Checking the field current draw

Checking the charging system resistance

Alternator system with ammeter in the circuit

4. Open diode rectifiers.

REGULATOR POINTS BURNED OR STUCK

1. Regulator set too high.
2. Poor ground connections.
3. Shorted generator field.
4. Regulator air gap incorrect.

CHRYSLER IMPORTS

Charging System

ALTERNATOR

Disassembly

1. Place a soldering iron on the bearing box for approximately 3-4

minutes to heat it, then pull out the bolts and insert a flat tip tool between the stator and front bracket and separate them.

NOTE: The bearing box must be heated or the bearing cannot be pulled out.

2. Separate the front and rear sections, being careful not to lose the stopper spring that fits around the circumference of the rear bearing.

3. Remove the pulley nut, then disassemble the pulley, rotor and front bracket.

4. The rear bearing can be removed by using a bearing puller.

5. Remove the nut of the B terminal and the insulation bushing. Remove the rectifier retaining screws and the brush holder retaining screw. Separate the rear bracket and stator.

6. Remove the IC regulator.

7. Remove the solder from the rectifier and stator leads.

NOTE: Do not use the soldering iron for more than 5 seconds as the rectifier may be damaged if overheated.

8. The brush may be removed by removing the solder from the pigtail.

ROTOR

Testing

1. Using an ohmmeter, check for continuity at the slip end rings. If there is no continuity, replace the rotor.

2. Using an ohmmeter, make an insulation test. Check for continuity between the slipring and the rotor core. If continuity exists, replace the rotor.

3. Measure the slipring outer diameter for wear. Minimum diameter is 1.18 in. (30mm).

STATOR

Testing

1. Using an ohmmeter, make a continuity test between the stator lead wires. If there is no continuity, replace the stator.

2. Using an ohmmeter, make an insulation test between the stator core and the lead wire. If the continuity exists, replace the stator.

DIODE

Testing

1. Using an ohmmeter, perform a continuity test on diodes in both directions.

2. Replace as necessary.

Exploded view of the Chrysler alternator—3.0L engine

BRUSHES

Testing

1. Check for smooth movement of the brush and clean the brush holder if necessary.

2. Check for brush wear by looking at the wear limit line on the brush and replace if necessary.

Assembly

1. Assembly of the alternator is the

reverse of disassembly with the following instructions:

2. When installing the front bearing, use a socket which exactly fits the outer race of the bearing, then use a hand press or vise and press the bear-

17 CHARGING AND STARTING IMPORT

ing in evenly. When pressing the rear bearing on, first heat the rear bracket, then press it so that the groove at the bearing circumference is at the slipping side. When soldering a new brush, solder the pigtail so that the wear limit line of the brush projects 0.079–0.118 in. out from the end of the brush holder. Fit the stopper spring into the eccentric groove of the rear bearing circumference. The protruding part of the spring should be fit into the deepest part of the groove. This makes assembly much easier.

3. Before assembly, use a finger to push the brush into the brush holder, then pass a wire through the hole and secure the brush into position. After reassembly, manually turn the pulley to make sure the rotor turns easily.

ISUZU

Charging System

Troubleshooting

1. Measure the resistance between **F**

and **E** terminals (rotor coil resistance): The rotor coil circuit is normal if resistance measured across the terminals is 5 ohms. If resistance is higher than 5 ohms, the trouble is poor contact between the brushes and commutator. If no continuity exists between terminals **F** and **E**, the trouble is either an open coil rotor circuit, brush sticking or a broken lead wire. If resistance is lower than 5 ohms, it may be an indication of rotor coil layer short or the circuit being grounded.

2. Test the rectifying diodes in the following manner: Connect the positive (+) lead of a tester to the alternator **N** terminal and the tester negative (–) lead to the alternator **A** terminal. If there exists a continuity between terminals, it indicates that 1 or more of the 3 diodes in the positive side are shorted. Connect the positive (+) lead of a tester to the alternator **E** terminal and the tester negative (–) lead to the alternator **N** terminal. If there exists a continuity, it indicates that 1 or more of the 3 diodes in the negative side are shorted.

ALTERNATOR Disassembly GASOLINE ENGINE

1. Remove the through bolts and disconnect the lead wires at the connector.

2. Separate the alternator assembly into front and rear sections. The stator should be on the rear side.

3. Carefully clamp the rotor in a vise and remove the pulley nut, then remove the pulley fan and rotor.

4. Remove the bearing retainer screws, then remove the ball bearing.

5. Remove the rear side nuts, then remove the stator from the rear cover together with the diodes, brush and capacitor.

6. Unsolder the diode-to-stator coil connections, then separate the diodes from the stator together with the brush and capacitor.

7. Remove the screws retaining the brush holder, then remove the diodes, brush and capacitor.

DIESEL ENGINE

1. If so equipped, remove the vacu-

17 CHARGING AND STARTING IMPORT

um pump attaching bolts, then hold the center plate and remove the vacuum pump in direction in line with the rotor shaft.

2. Remove the brush cover and the brush attaching bolts, then remove the brush from the holder.

3. Remove the through bolts and separate the body into front and rear sections.

NOTE: When separating, be careful so that the stator coils do not come off the rear cover. Do not damage the oil seal when removing the rear cover. Taping the splines could provide some protection.

4. Carefully clamp the rotor assembly in a vise and remove the pulley nut.

5. Separate the pulley front cover and rotor, then remove the spacer and ball bearing.

6. Remove the bearing retaining screws from the front cover, then remove the bearing.

7. Remove the terminal bolt and nut, then remove the lead wire.

8. Remove the nuts securing the B terminal and diode holder, then remove the screw inside the stator. Separate the stator and rear cover.

NOTE: Observe the position of the insulation washers for reassembly.

9. Remove the stator, then separate the diodes from the stator by melting the solder on the stator coil, diode and N terminal leads. When melting the solder, hold the lead wire with long nose pliers to prevent heat from being transferred to the diodes.

10. Remove the holder plate and brush holder.

11. Melt away the solder on the IC holder plate terminal, then remove the IC regulator assembly.

12. If necessary, the vacuum pump may be disassembled by removing the center plate, exposing the rotor and vane.

ROTOR

Testing

1. Using an ohmmeter, check for continuity at the slip end rings. If there is no continuity, replace the rotor.

2. Using an ohmmeter, make an insulation test. Check for continuity between the slipring and the rotor core. If continuity exists, replace the rotor.

3. Measure the slipring outer diameter for wear. Minimum diameter is 1.18 in. (30mm).

STATOR

Testing

1. Using an ohmmeter, make a continuity test between the stator lead wires. If there is no continuity, replace the stator.

2. Using an ohmmeter, make an insulation test between the stator core and the lead wire. If the continuity exists, replace the stator.

DIODE

Testing

1. Using and ohmmeter, perform a continuity test on diodes in both directions.

2. Replace as necessary.

BRUSH

Testing

1. Check for smooth movement of the brush and clean the brush holder if necessary.

2. Check for brush wear by looking at the wear limit line on the brush and replace if necessary.

Assembly

GASOLINE ENGINE

1. Assembly of the alternator is the reverse of disassembly with the following instructions.

2. Before assembling the front and rear sections, insert a wire into the hole in the rear face of the rear cover from the outboard side to support the brush in the raised position, then insert the front section to which the rotor is assembled

DIESEL ENGINE

1. Assembly of the alternator is the reverse of disassembly with the following instructions: Resolder the IC regulator lead wires. To prevent heat from being transferred to the diodes, use long nose pliers to hold the stator coil leads and diode leads and solder as quickly as possible.

2. Carefully clamp the rotor in a vise and torque the pulley nut to 33-43 ft. lbs.

3. Place some type of guide bar through the holes in the front cover and rear cover flange for alignment, then, install the through bolts. Make sure the brush is installed in the brush holder correctly.

4. If the vacuum pump was disassembled, position the rotor, with the serrated boss turned up, on the center plate and housing. Install the vanes into the slits in the rotor. The vanes should be installed with the camfered side turned outward.

Exploded view of the alternator's vacuum pump—Isuzu diesel engine

Testing the diodes

5. Install the housing, making sure the O-ring is not projected beyond the slot in the center plate. If the holes in the housing and center plate are not in alignment, adjust by turning the housing slightly, then, tighten the retaining bolts.

6. Add engine oil (around 5cc) through the filler port and make sure the pulley can be turned smoothly by hand.

MAZDA

Charging System

ALTERNATOR

Checking Regulated Voltage With No Load

1. Disconnect the wiring connected to alternator terminal B.

2. Connect an ammeter (more than 40 A) between the alternator terminal B and the battery positive terminal.

3. Connect a voltmeter between alternator terminal L and ground.

4. Start the engine and increase the engine speed to approximately 2000 rpm. Turn off all unnecessary electrical loads and read the value shown on the ammeter.

5. When the amperage in Step 4 is less than 5 amp., read the voltage (regulated voltage) of terminal L. The reg-

Checking the charging system

Checking the current output

ulated voltage should be 14.1–14.7 V.

Checking Output Current

1. Disconnect the wiring connected to the alternator terminal B.
2. Connect an ammeter (more than 40 amp) between the alternator terminal B and the battery positive terminal.
3. Start the engine and increase the engine speed to more than 2500 rpm and read the maximum value shown on the ammeter. Apply all electrical loads. If the value shown on the ammeter is more than 90% of the rated output, the alternator is normal.

Disassembly

1986–88

1. Place a soldering iron on the bearing box for approximately 3–4 minutes to heat it, then pull out the bolts and insert a flat tip tool between the stator and front bracket and separate them.

NOTE: The bearing box must be heated or the bearing cannot be pulled out.

2. Separate the front and rear sections, being careful not to lose the stopper spring that fits around the circumference of the rear bearing.
3. Remove the pulley nut, then disassemble the pulley, rotor and front bracket.
4. The rear bearing can be removed by using a bearing puller.
5. Remove the nut of the B terminal and the insulation bushing. Remove the rectifier retaining screws and the

brush holder retaining screw and then separate the rear bracket and stator.

6. Remove the IC regulator.

7. Remove the solder from the rectifier and stator leads.

NOTE: Do not use the soldering iron for more than 5 seconds as the rectifier may be damaged if overheated.

8. The brush may be removed by removing the solder from the pigtail.

1989–90

1. Remove the alternator through bolts and separate the rear case/stator assembly from the front case/rotor assembly.
2. Secure the rotor and remove the pulley nut, the washer and the pulley.
3. Pull the rotor from the front case.
4. Remove the front bearing retainer-to-front case bolts, the retainer and the bearing.
5. From the rear case, remove the stator, the brush holder/rectifier assembly-to-rear case nuts/washers, the brush holder assembly and the rectifier.

ROTOR

Testing

1. Using an ohmmeter, check for continuity at the slip end rings. If there is no continuity, replace the rotor.
2. Using an ohmmeter, make a ground test. Check for continuity between the slipring and the rotor core. If continuity exists, replace the rotor.
3. Measure the slipring outer diam-

eter for wear. Minimum diameter is 1.18 in. (30mm).

STATOR

Testing

1. Using an ohmmeter, make a continuity test between the stator lead wires. If there is no continuity, replace the stator.

2. Using an ohmmeter; make a ground test between the stator core and the lead wire. If the continuity exists, replace the stator.

DIODE

Testing

1. Using and ohmmeter, perform a continuity test on diodes in both directions.

2. Replace as necessary.

BRUSHES

Testing

1. Check for smooth movement of

the brush and clean the brush holder, if necessary.

2. Check for brush wear by looking at the wear limit line on the brush and replace, if necessary.

Assembly

1986-88

1. Assemble the alternator by reversing the order of disassembly, while observing the following instructions:

2. When installing the front bearing, use a socket which exactly fits the outer race of the bearing, then use a hand press or vise to press the bearing in evenly.

3. When pressing the rear bearing on, first heat the rear bracket, then press it so the groove at the bearing circumference is at the slipping side.

4. When soldering a new brush, solder the pigtail so the wear limit line of the brush projects 0.079-0.118 in. out from the end of the brush holder.

5. Install the stopper spring into the eccentric groove of the rear bearing circumference. The protruding part of the spring should be fit into the

deepest part of the groove; this makes assembly much easier.

6. Before assembly, use a finger to push the brush into the brush holder, then, pass a wire through the hole in the brush holder and secure the brush into position.

7. After assembly, manually turn the pulley to make sure the rotor turns easily.

1989-90

1. Install the front bearing into the front cover.

2. Install the front bearing retainer and torque the bolts to 26-39 inch lbs. (2.9-4.4 Nm).

3. Install the rotor into the front case. Install the pulley and torque the nut to 43-58 ft. lbs. (58-78 Nm).

4. Install the rectifier, the brush holder assembly and stator to the rear housing. Torque the bolts to 26-39 inch lbs. (2.9-4.4 Nm).

5. Using a wire, depress the brushes into the brush holder and secure them in place.

6. Assemble the alternator halves.

7. Install the through bolts and

torque to 35-48 ft. lbs. (3.9-5.4 Nm).

8. Remove the wire securing the brushes.

9. Manually, turn the pulley to make sure the rotor turns easily.

MITSUBISHI

Charging System

ALTERNATOR

Troubleshooting (On Vehicle)

1. Place the ignition switch in the OFF position.

2. Disconnect the battery ground cable.

3. Disconnect the cable from terminal B of the alternator and connect an ammeter between the terminal B and the cable.

4. Connect a voltmeter between terminal B (+) and ground (-).

5. Set the engine tachometer.

6. Connect the battery ground cable to the battery. The voltmeter should indicate the battery voltage.

7. Start the engine.

8. Turn ON the lamps, accelerate the engine to the speed specified and measure the output current. Check it against the specifications.

Disassembly

1. Remove alternator from vehicle.

2. Remove the through bolts from the alternator body.

3. Insert an appropriate pry tool between the front bracket and stator. Pry the front bracket away from the stator. Remove the front bracket along with the rotor.

NOTE: If the tool is inserted too deeply, the stator coil might be damaged.

4. Hold the rotor in a vise and remove the pulley nut. Then remove the pulley, fan, spacer and seal. Remove

Exploded view of the Mitsubishi alternator—2.6L engine

Exploded view of the Mitsubishi alternator—3.0L engine

17 CHARGING AND STARTING IMPORT

the rotor from the front bracket and remove the seal.

5. Unsolder the rectifier from the stator coil lead wires and remove the stator assembly.

NOTE: Make sure the solder is removed quickly (in less than 5 seconds). If a diode is heated to more than 150°C, it might be damaged.

6. Remove the condenser from terminal B.

7. Unsolder the plates B and L from the rectifier assembly.

8. Remove the mounting screw and terminal B bolt and remove the electronic voltage regulator and brush holder. The regulator and brush holder cannot be separated.

9. Remove the rectifier assembly.

10. When only a brush or brush spring is to be replaced, it is not necessary to remove the stator, etc. Raise the brush holder assembly and unsolder the wire pigtail of the brush and remove the brush.

NOTE: Be very careful when bending the plates B and L so as not to disturb the rectifier moulding.

Testing

1. Check the outside circumference

of the slipring for dirtiness and roughness. Clean or polish with armature paper, if required. A badly damaged slipring or a slipring worn down beyond the service limit should also be replaced. The service limit for the slipring outside diameter is 1.268 in.

2. Check for continuity between the field coil and slipring. If there is not continuity, the field coil is defective and the rotor must be replaced.

3. Check for continuity between the slipring and the shaft (or core). If there is continuity, the rotor assembly must be replaced.

4. Check for continuity between the leads of the stator coil. If there is no continuity, the stator coil is defective.

5. Check for an open circuit between the stator coil leads and the stator core. If there is continuity between the stator core and the coil leads, the stator assembly must be replaced.

6. Check for continuity between the positive (+) heat sink and the stator coil lead connection terminal with a circuit tester. If there is continuity in both directions, the diode is short circuited and the rectifier assembly must be replaced.

7. Perform Step 6 between the negative (-) heat sink and the stator coil lead connection.

8. Using a circuit tester, check the 3 diodes for continuity in both direc-

tions. If there is either continuity or an open circuit in both directions, the diode is defective and must be replaced.

9. Measure the length of the brush. If it is worn below 0.315 in., it must be replaced.

Assembly

1. Assembly is the reverse of disassembly with the following instructions:

2. Be sure to install both the front and rear seals on the front bearing. To install the rotor assembly in the rear bracket, push the brushes into the brush holder, insert a wire to hold them in the raised position and install the rotor. Remove the wire.

NISSAN

Charging System

ALTERNATOR

Disassembly

1. On diesel engine models only, remove the vacuum pump.

2. Remove the through bolts and separate the front cover from the rear cover.

3. Place the rear cover side of the rotor in a vise and remove the pulley nut and pulley.

4. Remove the screws from the bearing retainer.

5. Remove the attaching nuts and take out the stator assembly.

6. Use a bearing puller or a press and pull the rear bearing from the rotor assembly.

NOTE: The bearing cannot be reused and must be replaced with a new one.

7. To remove the stator, disconnect the stator coil lead wires from the diode terminals, using a soldering iron.

8. On diesel engine models, check the oil seal for leakage. If replacement is needed, pry out the old seal, apply engine oil to the new seal and install in position.

ROTOR

Testing

1. Using an ohmmeter, check for continuity at the slip end rings. If there is no continuity, replace the rotor.

2. Using an ohmmeter, make an insulation test. Check for continuity between the slipring and the rotor core. If continuity exists, replace the rotor.

3. Measure the slipring outer diameter for wear. Minimum diameter is 1.18 in. (30mm).

STATOR

Testing

1. Using an ohmmeter, make a continuity test between the stator lead wires. If there is no lead wires, replace the stator.

2. Using an ohmmeter, make an insulation test between the stator core and the lead wire. If the continuity exists, replace the stator.

DIODE

Testing

1. Using an ohmmeter, perform a continuity test on diodes in both directions.
2. Replace diodes as necessary.

BRUSH

Testing

1. Check for smooth movement of the brush and clean the brush holder if necessary.
2. Check for brush wear at the wear limit line on the brush and replace if necessary.

Assembly

1. Assembly of the alternator is the reverse of disassembly with the following instructions: Solder each stator coil lead wire to the diode assembly terminal as quickly as possible. When soldering the brush lead wire, position the brush so that it extends 0.43 in. from the brush holder and wrap the coil lead wire at least 1.5 times around the terminal groove. Solder the outside of the terminal.
2. Tighten the pulley nut to 29-43 ft. lbs.

3. Before installing the front and rear sides of the alternator, push the brush up and retain the brush by inserting a wire from the outside into a lift hole. After installing the front and rear sides of the alternator, pull the brush lift by pushing towards the center.

NOTE: Do not pull brush lift by pushing towards the outside of the cover as it will damage the slipring as it slides.

SUZUKI/GEO

Charging System

ALTERNATOR

Disassembly

TRACKER

1. Place alignment matchmarks on the cases.
2. Remove the through bolts from the generator.
3. Using a 200W soldering iron, position it against the bearing box at the rear of the alternator housing and heat the bearing box to a temperature of 122-140°F (50-60°C).
4. Using a medium prybar, position it between the stator core and the front housing, then, separate the front housing from the rear housing.
5. Position the rotor/front housing into a soft jawed vise.
6. Remove the pulley nut and the pulley.
7. Remove the front housing from the rotor.
8. Remove the front bearing by performing the following procedures:
 - a. Remove the front bearing retainer screws and the retainer.
 - b. Using a shop press, press the bearing from the front housing.
9. Remove the stator-to-rear housing screws, the battery terminal nut and the stator.
10. If necessary to remove the brushes from the brush holder, use a soldering iron to unsolder the brush wire(s).
11. Remove the rectifier and condenser assembly from the rear housing.

Remove the pulley nut and the pulley.

Remove the front housing from the rotor.

Remove the front bearing by performing the following procedures:

a. Remove the front bearing retainer screws and the retainer.

b. Using a shop press, press the bearing from the front housing.

Remove the stator-to-rear housing screws, the battery terminal nut and the stator.

If necessary to remove the brushes from the brush holder, use a soldering iron to unsolder the brush wire(s).

Remove the rectifier and condenser assembly from the rear housing.

Remove the pulley nut and the pulley.

Remove the front housing from the rotor.

Remove the front bearing by performing the following procedures:

a. Remove the front bearing retainer screws and the retainer.

b. Using a shop press, press the bearing from the front housing.

Remove the stator-to-rear housing screws, the battery terminal nut and the stator.

If necessary to remove the brushes from the brush holder, use a soldering iron to unsolder the brush wire(s).

Remove the rectifier and condenser assembly from the rear housing.

4. Remove the rectifier holder screws and the holder.

5. Remove the terminal insulator.

6. Loosen the alternator pulley nut and the pulley.

NOTE: To prevent damage to the rotor shaft, do not loosen the pulley nut more than 1/2 turn.

7. Remove the nuts from the rear end frame. Using a puller, remove the rear end frame.

8. Remove the rotor from the drive end frame.

9. If necessary, remove the front bearing by removing the screws from the bearing retainer.

10. If necessary, remove the rear bearing by using a puller. Remove the rear bearing with the cover from the rotor shaft.

Testing

TRACKER

1. Using an ohmmeter, check the resistance between the rotor sliprings; if there is no continuity, replace the rotor.

2. Using an ohmmeter, check the resistance between the rotor slipring and the rotor; if there is continuity, replace the rotor.

3. Inspect the rotor sliprings for scoring or roughness; if rough or scored, replace the rotor.

4. Using an ohmmeter, check for continuity between the leads; if there is no continuity, replace the stator.

5. Using an ohmmeter, check for continuity between the leads and the stator core; if there is continuity, replace the stator.

6. Inspect the brushes for wear; the

brush wear limit is 0.55 in. (14mm), if worn past the limit, replace the brushes.

7. Using an ohmmeter, check for continuity, in both directions, between the upper and lower rectifier bodies and each diode lead; if continuity exists in both directions, replace the rectifier.

SAMURAI AND SIDEKICK

1. Using an ohmmeter, check for continuity between the sliprings. Standard resistance is 2.8–3.0 ohms; if there is no continuity, replace the rotor.

2. Using an ohmmeter, check that there is no continuity between the slipring and rotor; if there is continuity, replace the rotor.

3. Using an ohmmeter, check all leads for continuity. If there is no continuity, replace the drive end frame assembly.

4. Using an ohmmeter, check for continuity between the coil leads and the drive end frame; if there is continuity, replace the drive end frame assembly.

5. Measure the exposed brush length and replace, if necessary. Minimum length is 0.200 in. Also check that the brush moves smoothly in the brush holder.

6. Inspect the front and rear bearings for roughness and replace, if necessary.

Assembly

TRACKER

1. Install the rectifier and condenser assembly into the rear housing.

2. If the brushes were removed, be sure to solder them to the regulator terminal.

3. Using a stiff wire, depress the brushes into the holder and insert the wire, through the hole in the rear housing, to hold the brushes in place.

4. Install the stator to the rear housing.

5. Using a shop press, press the bearing into the front housing.

6. Install the bearing retainer to the front housing.

7. Using a 200W soldering iron, heat the bearing box of the rear housing to 122–140°F (50–60°C).

8. Install the rotor into the front housing, the pulley and the pulley nut; torque the nut to 48 ft. lbs. (65 Nm).

9. Align the matchmarks and assemble the front housing/rotor assembly to the rear housing.

10. Install the through bolts and remove the brush support wire.

11. Make sure the rotor turn freely within the assembly.

SAMURAI AND SIDEKICK

1. If it is necessary to replace the rear bearing, use a shop press and press the rear bearing and cover onto the rotor shaft.

2. Install the rotor to the drive end frame.

3. Using a plastic hammer, lightly tap the rear end frame on the drive end frame and install the nuts.

4. Install the alternator pulley and torque to 37–47 ft. lbs.

5. Install the terminal insulators on the lead wires.

6. Install the rectifier holder with the screws.

7. If it is necessary to install a new

19. Rear end cover

Exploded view of the Suzuki alternator

brush, unsolder and remove the brush and spring. Put the new brush wire through the spring and insert it into the brush holder. Solder the wire to the brush holder and cut off any excess.

8. Install the brush holder with the IC regulator and the screws to the IC regulator. Install the retaining screws and the brush holder cover to the rear end frame.

9. Install the end cover with the retaining nuts and install the terminal insulator and nut.

10. Make sure the rotor rotates smoothly.

11. Remove the nuts and end cover.

12. Remove the screws, the brush holder and brush holder cover.

13. Remove the screws and the IC regulator.

14. Remove the rectifier holder screws and the holder.

15. Remove the terminal insulator(s).

16. To remove the pulley and nut, use tool 09820-63010 to perform the following procedure:

a. Hold the tool at point A with a torque wrench and tighten at point B clockwise to 29 ft. lbs. (39 Nm).

b. Confirm that the tool A is secured to the pulley shaft.

c. Grip tool C in a vise and install the alternator into the special tool C.

d. Loosen the pulley nut by turning tool A counter-clockwise.

NOTE: To prevent damage to the rotor shaft, do not loosen the pulley nut more than 1/2 turn.

e. Turn the tool at point B and remove all the tool components.

f. Remove the pulley nut and the pulley.

7. Remove the nuts from the rear end frame. Using a puller, tool 09286-46011, remove the rear end frame.

8. Remove the rotor from the drive end frame.

9. If necessary, remove the front bearing by removing the screws from the bearing retainer.

10. If necessary, remove the rear bearing by using a puller, tool 09820-00020. Remove the rear bearing with the cover from the rotor shaft.

LAND CRUISER

1. Remove the through bolts.

2. Using a prybar, pry the drive end frame/rotor assembly from the stator.

3. Mount the rotor assembly into a soft jawed vise.

4. Remove the pulley nut, the spring washer, the pulley and fan from the rotor.

5. Remove the spacer collar, drive end frame, the spacer ring and snapping.

6. From the rectifier end frame, remove the nuts, the condenser and the terminal insulators.

7. Remove the rectifier end frame and the insulator washer from the rectifier holder stud.

8. Using needle-nose pliers to hold

the IC regulator terminal, unsolder the terminals.

NOTE: Protect the rectifiers from heat.

9. Using needle-nose pliers to hold the stator coil lead, unsolder the leads.

Testing

EXCEPT LAND CRUISER

1. Using an ohmmeter, check for continuity between the sliprings; standard resistance is 2.8–3.0 ohms. If there is no continuity, replace the rotor.

2. Using an ohmmeter, check that there is no continuity between the slipring and rotor. If there is continuity, replace the rotor.

3. Using an ohmmeter, check all leads for continuity. If there is no continuity, replace the drive end frame assembly.

4. Using an ohmmeter, check that there is no continuity between the coil leads and the drive end frame. If there is continuity, replace the drive end frame assembly.

5. Measure the exposed brush length and replace, if necessary; minimum length is 0.059 in. (1.5mm). Also check that the brush moves smoothly in the brush holder.

6. Inspect the front and rear bearings for roughness and replace if necessary.

LAND CRUISER

1. Using an ohmmeter, check for

continuity between the sliprings; standard resistance is 2.8–3.0 ohms. If there is no continuity, replace the rotor.

2. Using an ohmmeter, check that there is no continuity between the slipring and rotor. If there is continuity, replace the rotor.

3. Using an ohmmeter, check all leads for continuity; if there is no continuity, replace the stator.

4. Using an ohmmeter, check that there is no continuity between the coil leads and the stator core; if there is continuity, replace the stator.

5. Measure the exposed brush length and replace, if necessary; minimum length is 0.217 in. (5.5mm). Also check that the brush moves smoothly in the brush holder.

6. Inspect the front and rear bearings for roughness and replace if necessary.

7. Using an ohmmeter, inspect the diodes of the rectifier assembly; good diodes will show continuity in one direction and no continuity in the other direction.

Assembly

EXCEPT LAND CRUISER

1. If it is necessary to replace the rear bearing, use bearing installation and press the rear bearing and cover onto the rotor shaft.

2. Install the rotor to the drive end frame.

3. Using a plastic hammer, lightly tap the rear end frame on the drive end frame and install the nuts.

4. Install the pulley in the following manner:

a. Using the pulley onto the rotor shaft and tighten the pulley nut by hand.

b. Using tool 09820–63010, hold it at point **A** with a torque wrench and tighten tool **B** clockwise to 29 ft. lbs. (39 Nm).

c. Confirm tool **A** is secured to the pulley shaft.

d. Grip special tool **C** in a vise and then install the alternator to tool **C**.

e. To torque the pulley nut, turn tool **A** and tighten to 81 ft. lbs. (110 Nm).

f. Turn tool **B** and remove all the tool components.

5. Install the terminal insulators on the lead wires.

6. Install the rectifier holder with the screws.

7. If it is necessary to install a new brush, unsolder and remove the brush and spring. Put the new brush wire through the spring and insert it into

the brush holder. Solder the wire to the brush holder and cut off any excess.

8. Install the brush holder with the IC regulator and install the screws to the IC regulator. Install the retaining screws and the brush holder cover to the rear end frame.

9. Install the end cover with the retaining nuts and install the terminal insulator and nut. Make sure the rotor rotates smoothly.

LAND CRUISER

1. Using needle-nose pliers to hold the stator coil lead, solder the leads.

NOTE: Protect the rectifiers from heat.

2. Using needle-nose pliers to hold the IC regulator terminal, solder the terminals.

3. Install the rectifier end frame-to-rectifier holder by performing the following procedures:

a. Position the insulator washer onto the positive (+) stud of the rectifier holder.

b. Position both cushions onto the brush holder and alternator terminal.

c. Position the rectifier end frame onto the rectifier holder.

d. Position both terminal insulators onto the positive (+) studs of the rectifier holder.

e. Install the condensor and nuts.

4. Install the drive end frame, the fan and pulley to the rotor by performing the following procedures:

a. Install the snapring and spacer ring onto the rotor shaft.

b. Position the rotor into the soft jawed vise.

c. Install the drive end frame and spacer collar.

d. Install the fan, the pulley and spring washer onto the rotor shaft.

e. Torque the pulley nut to 65 ft. lbs. (88 Nm).

5. Assemble the drive end frame and the rectifier end frame by performing the following procedures:

a. Bend the rectifier lead wires back to clear the rotor.

b. Push the brushes into the holder, as far as they will go, and insert a stiff wire through the access hole, in the rectifier frame, to hold the brushes in place.

c. Assemble the drive end frame and the rectifier end frame.

d. Install the through bolts.

e. Remove the stiff wire from the access hole.

f. Turn the rotor to make sure it turns freely.

g. Seal the access hole.

VOLKSWAGEN

Charging System

ALTERNATOR

Disassembly

BOSCH

45 Amp and 65 Amp

1. Remove the alternator from the vehicle. Mount the unit in a suitable holding fixture.

2. Hold the alternator pulley and remove the pulley retaining nut.

3. Remove the pulley lockwasher, pulley fan spacer and pulley from the alternator assembly.

4. Remove the Woodruff® key from the rotor shaft.

5. From the rear of the alternator remove the brush holder retaining screws. Remove the brush holder.

6. To test the inner and outer brush circuits, use an ohmmeter and touch 1 test probe to the inner brush and the other test probe to the brush terminal. If continuity does not exist replace the brush assembly. Repeat the same test for the outer brush circuit.

7. Disconnect the capacitor electrical connection and remove the capacitor retaining screw. Remove the capacitor from its mounting on the alternator.

8. Remove the ground stud nut and stud washer.

9. Remove the alternator through bolts that retain the unit together.

10. Using the proper tool, separate the stator and the drive end shield.

11. To test the positive and negative rectifiers use tool C-3929-A or equivalent.

NOTE: Do not break the plastic cases of the rectifiers. These cases are for protection against corrosion. Be sure to always touch the test probe to the metal pin of the nearest rectifier.

12. Position the rear end shield and the stator assembly on an insulated surface. Connect the test lead clip to the alternator battery output terminal.

13. Plug in tool C-3829-A or equivalent. Touch the metal pin of each of the positive rectifiers with the test probe.

14. Reading for satisfactory rectifiers will be 1¾ amperes or more. Reading should be approximately the same and meter needle must move in the same direction for all 3 rectifiers.

Exploded view of the Bosch 45 amp and 65 amp alternators—Volkswagen

15. When some rectifiers are good and 1 is shorted, the reading taken at good rectifiers will be low and the reading at shorted rectifiers will be 0. Disconnect stator lead to rectifiers reading 0 and retest. Reading of good rectifiers will now be within satisfactory range.

16. When a rectifier is open, it will read approximately 1 ampere and good rectifiers will read within satisfactory range.

17. To test the negative rectifiers, connect the test clip of tool C-3829-A to the rectifier end housing.

18. Touch the metal pin of each of the negative rectifiers with the test probe.

19. Test specifications are the same

and test results will be approximately same as for positive case rectifiers except that the meter will read on opposite side of scale.

NOTE: If a negative rectifier shows a shorted condition, remove stator from rectifier assembly and retest. It is possible that a stator winding could be grounded to stator laminations or to an rectifier end shield which would indicate a shorted negative rectifier.

20. Remove the battery (B+) stud nut, stud lockwasher, stud flatwasher and stud insulator.

21. Remove the rectifier assembly retaining screws. Remove the stator as-

sembly along with the rectifier unit. Unsolder the stator to rectifier leads.

22. Check for continuity between stator coil leads. Press test probe firmly to each of 3 phase (stator) lead terminals separately. If there is no continuity, stator coil is defective. Replace stator assembly.

23. To test stator for ground, check for continuity between stator coil leads and stator coil frame. If there is continuity stator is grounded. Replace stator assembly.

24. Remove the rear bearing oil and dust seal. Check the rotor bearing surface for wear and scoring. Replace as required.

25. Remove the inner battery (B+) stud insulator.

Exploded view of the Bosch 90 amp alternator—Volkswagen

26. Press the rotor out of the drive end shield and remove the spacer.

27. Check outside circumference of slipring for dirtiness and roughness. Clean or polish with fine sandpaper, if required. A badly roughened slipring or a worn down slipring should be replaced.

28. Check for continuity between field coil and sliprings. If there is no continuity, field coil is defective. Replace rotor assembly.

29. Check for continuity between sliprings and shaft (or core). If there is continuity, it means that coil or slipring is grounded. Replace rotor assembly.

30. Using a puller remove the rotor bearing.

31. Remove the front bearing from

the drive end shield by removing the front bearing retaining screws.

32. Press out the drive end shield bearing. Remove the front drive bearing from the front drive end shield.

90 Amp

1. Remove the alternator from the vehicle. Position the unit in a suitable holding fixture.

2. Remove the pulley nut and lockwasher. Remove the alternator pulley.

3. Remove the pulley to fan spacer and pulley fan.

4. Remove the Woodruff key from the rotor shaft.

5. From the rear of the alternator disconnect the electrical terminal from the capacitor. Remove the capacitor retaining screw and the capacitor.

6. Remove the brush holder retaining screw and remove the brush holder from its mounting on the rear of the alternator.

7. Remove the alternator through bolts. Using a suitable tool pry between the stator and the drive end shield and carefully separate the assembly.

8. Press the rotor out of the drive end shield and remove the spacer. Remove the pulley fan spacer.

9. Remove the front alternator drive end bearing screws.

10. Remove the drive end shield bearing retainer and press out the drive end shield bearing.

11. Remove the front drive bearing from the front of the drive end shield.

12. To test the positive and negative

rectifiers use tool C-3929-A or equivalent.

NOTE: Do not break the plastic cases of the rectifiers. These cases are for protection against corrosion. Be sure to always touch the test probe to the metal pin of the nearest rectifier.

13. Position the rear end shield and the stator assembly on an insulated surface. Connect the test lead clip to the alternator battery output terminal.

14. Plug in tool C-3829-A or equivalent. Touch the metal pin of each of the positive rectifiers with the test probe.

15. Reading for satisfactory rectifiers will be $1\frac{3}{4}$ amperes or more. Reading should be approximately the same and meter needle must move in same direction for all 3 rectifiers.

16. When some rectifiers are good and 1 is shorted, the reading taken at good rectifiers will be low and the reading at shorted rectifiers will be 0. Disconnect stator lead to rectifiers reading 0 and retest. Reading of good rectifiers will now be within satisfactory range.

17. When a rectifier is open it will read approximately 1 ampere and the good rectifiers will read within satisfactory range.

18. Touch the metal pin of each of the negative rectifiers with the test probe.

19. Test specifications are the same and the test results will be approximately same as for positive case rectifiers except that the meter will read on opposite side of scale.

NOTE: If a negative rectifier shows a shorted condition remove stator from rectifier assembly and retest. It is possible that a stator winding could be grounded to stator laminations or to a rectifier end shield, which would indicate a shorted negative rectifier.

20. Unsolder the stator to rectifier leads. Mark the stator coil frame, to aid in reinstallation of the stator. Remove the stator from the rectifier end shield assembly.

21. Remove the 3 rectifier assembly mounting screws. Remove the rectifier assembly.

22. Remove the inner battery (B+) stud insulator.

23. Remove the D+ stud insulator, stud nut, stud flatwasher and stud insulating washer.

24. Remove the rear bearing oil and dust seal. Check the rotor bearing surface for scoring.

25. Using puller C-4068 or equivalent, remove the rear rotor bearing.

26. Check outside circumference of slipring for dirtiness and roughness. Clean or polish with fine sandpaper, as required. A badly roughened slipring or a worn down slipring should be replaced.

27. To check for an open rotor field coil, connect an ohmmeter to sliprings. Ohmmeter reading should be between 1.5-2.0 ohms on rotor coils at room ambient conditions. Resistance between 2.5-3.0 ohms would result from alternator rotors that have been operated on vehicle at higher engine compartment temperatures. Readings above 3.5 ohms would indicate high resistance rotor coils and further testing or replacement may be required.

28. To check for a shorted field coil connect an ohmmeter to sliprings. If reading is below 1.5 ohms field coil is shorted.

29. To check for a grounded rotor field coil connect an ohmmeter from each slipring to rotor shaft.

NOTE: Ohmmeter should be set for infinite reading when probes are apart and 0 when probes are touching. The ohmmeter should read infinite. If reading is 0 or higher, rotor is grounded.

30. Check for continuity between leads of stator coil. Press test probe firmly to each of 3 phase (stator) lead terminals separately. If there is no continuity, stator coil is defective. Replace stator assembly.

31. To test the stator for ground check for continuity between the stator coil leads and the stator coil frame. If there is no continuity the stator is grounded and must be replaced.

32. To test the inner and outer brush circuit, use an ohmmeter and touch 1 test probe to the inner brush and the other test probe to the brush terminal. If continuity does not exist replace the brush assembly. Repeat the same procedure for the outer brush.

Assembly

45 Amp and 65 Amp

1. Be sure to check all parts for wear and replace the defective components as required.

2. Install the rear rotor bearing oil and dust seal.

3. Install the inner alternator battery terminal insulator.

4. Solder the stator leads to the rectifier assembly; be sure to use needle nose pliers as a heat sink.

5. Position the stator and rectifier assembly. Install the rectifier mounting screws, both terminal insulators, the insulator washer, the insulator lockwasher and the insulator nut.

6. Position and press the front bearing into the drive end shield. Install the bearing retainer.

7. Position the drive end shield and spacer over the rotor. Press the drive end shield onto the rotor.

8. Install the rectifier end shield over the drive end shield. Install the through bolts and tighten.

9. Install the capacitor and terminal plug onto the alternator assembly.

10. Push the brushes into the brush holder and install the brush holder onto the alternator assembly.

11. Install the Woodruff key into the shaft and the fan over the shaft.

12. Install the drive pulley-to-fan spacer, the pulley, the lockwasher and the nut over the shaft. Secure the pulley and tighten the nut.

90 Amp

1. Be sure to check all parts for wear and replace the defective components as required.

2. Install the rear rotor bearing oil and dust seal.

3. Install the inner alternator battery B+ terminal insulator.

4. Position the rectifier assembly. Install the rectifier mounting screws, the insulator, the insulator washer, the insulator lockwasher and the insulator nut.

5. Position the stator assembly into the rectifier end shield. Align the scribe marks on the stator and the rectifier end shield.

6. Solder the stator leads to the rectifier assembly; be sure to use needle nose pliers as a heat sink.

7. Position and press the front bearing into the drive end shield. Install the bearing retainer and the pulley fan spacer onto the drive end shield.

8. Position the drive end shield and spacer over the rotor. Using a socket wrench, press the drive end shield onto the rotor.

9. Install the rectifier end shield and stator assembly into the drive end shield and rotor assembly. Install the through bolts and tighten.

10. Push the brushes into the brush holder and install the brush holder onto the alternator assembly.

11. Install the capacitor and terminal plug onto the alternator assembly.

12. Install the Woodruff key into the shaft and the fan over the shaft.

13. Install the drive pulley-to-fan spacer, the pulley, the lockwasher and the nut over the shaft. Secure the pulley and tighten the nut.

SWITCHES AND SOLENOIDS

Magnetic Switches

Magnetic switches serve only to make contact for the starter motor. Usually, such switches are located on the inner fender panel, although they are found mounted on the starter in a few cases.

MAGNETIC SWITCHES WITH TWO CONTROL TERMINALS

On this type of magnetic switch current is supplied from the ignition switch or transmission neutral button to 1 of the magnetic switch control terminals. The other control terminal is connected to the transmission neutral safety switch (on the transmission) where it is grounded.

MAGNETIC SWITCHES WITH IGNITION RESISTOR BYPASS TERMINALS

All normally use a magnetic switch with a single control terminal. The second terminal is an ignition resistor bypass terminal.

SOLENOIDS WITHOUT RELAYS

This type of starter solenoid is always mounted on the starter. Makes electrical contact for the starter and pulls the starter and drive clutch into mesh with the flywheel. The Chrysler reduction gear starter has this solenoid embodied in the starter housing.

There is only 1 control terminal on the solenoid and the ignition bypass terminal is usually marked **R** or **IGN**, if it is used.

SOLENOIDS WITH SEPARATE RELAYS

The solenoid itself is always mounted

on the starter. In addition to making contact for the starter, it also pulls the starter drive clutch gear into mesh with the flywheel. A single control terminal is used on the solenoid itself. The relay is usually found mounted to the inner fender panel or on the firewall.

SOLENOIDS WITH BUILT-IN RELAYS

These units are always mounted on the starter and are connected, through linkage, to the starter drive clutch. The relay portion is built into and integral with the front end of the solenoid assembly.

NEUTRAL SAFETY SWITCHES

The purpose of the neutral safety switch is to prevent the starter from cranking the engine except when the transmission is in neutral or park.

On some vehicles, the neutral safety switch is located on the transmission. It serves to ground the solenoid or magnetic switch, whichever is used.

On other vehicles, the neutral safety switch is located on the steering column, where it contacts the shift mechanism within the steering column or on the shift linkage when a console is used.

Some manual transmission models have a clutch linkage safety switch to prevent starter operation unless the clutch pedal is depressed.

On most vehicles, the neutral safety switch and the backup light switch are combined into a single switch mechanism.

Troubleshooting Neutral Safety Switches Quick Test

If the starter fails to function and the neutral safety switch is to be checked, a jumper can be placed across its terminals. If the starter then functions, the safety switch is defective.

In the case of neutral safety switches with 1 wire, the wire must be grounded for testing purposes. If the

starter works with the wire grounded, the switch is defective.

NEUTRAL SAFETY SWITCH/BACK-UP LIGHT SWITCH

When the neutral safety switch is built in combination with the back-up light switch, the quickest way to determine which terminals are for the back-up lights is to take a test lamp/jumper wire and cross from a hot wire to a neutral wire. The wires which light the back-up lamps should be ignored when testing the neutral safety switch. Once the back-up light wires have been located, jump the other pair of wires to test the neutral safety switch. If the starter functions only when the jumper is placed across both wires, the neutral safety switch is defective or requires adjustment.

IMPORT STARTING SYSTEMS

STARTER MOTOR TESTING

The starter circuit should be divided and tested in 4 separate phases:

1. Cranking voltage check
2. Amperage draw
3. Voltage drop on grounded side
4. Voltage drop on battery side

NOTE: The battery must be in good condition for this test to have significance. To accurately check battery condition, use equipment designed to measure its capacity under a load. Instructions accompanying the equipment should be followed.

Sectional view of the starter solenoid mounted on a starter motor

Voltmeter connected to battery for cranking voltage test

Cranking Voltage

Connect voltmeter leads to prods tapped into the battery posts (observe polarity and reverse meter leads if necessary). Remove the high tension wire from the distributor cap and ground it to prevent engine starting. With electronic ignition, disconnect the control box harness from the distributor. Turn the key to the start position. Observe both voltmeter reading and cranking speed. The cranking speed should be even and at a satisfactory rate of speed, with a voltmeter reading of at least 9.6 volts for 12 volt systems.

Starter current indicator

Amperage Draw

The amount of current the starter motor draws is usually (but not always) associated with the mechanical problems involved in cranking the engine. (Mechanical trouble in the engine, frozen or worn starter parts, misaligned starter or starter components, etc.) Because starter motor amperage draw is directly influenced by anything restricting the free turning of the engine or starter, it is important that the engine and all components be at operating temperatures.

To measure starter current draw, remove the high tension wire from the center of the distributor cap and ground it. With electronic ignition, disconnect the control box harness from the distributor. A very simple and inexpensive starter current indicator is available. This indicator is an induction type gauge and shows, without disconnecting any wires, starter current draw.

Place the yoke of the meter directly over the insulated starter supply cable (cable must be straight for a minimum of 2 in.). Close the starter switch for about 20 seconds, watch the meter dial and record the average reading. If the indicator swings in the wrong direction, reverse the position of the meter.

The cranking amperage draw can vary from 150-400 amperes, depending on the engine size, engine compression and starter type.

NOTE: When starter specifications are not available, average starter draw amperage can be derived from testing a like starter unit, known to be operating satisfactorily.

More accurate equipment is available from many manufacturers. This equipment consists of a combination voltmeter, ammeter and carbon pile rheostat. When using this equipment, follow the equipment manufacturer's procedures and recommendations.

High amperage and lazy performance would suggest an excessively

Starter cable resistance tests

Positive engagement starter circuits

tight engine, friction in the starter or starter drive, grounded starter field or armature.

Normal amperage and lazy performance suggest high resistance or possibly poor connections somewhere in the starter circuit.

Low amperage and lazy or no performance suggest battery condition poor, bad cables or connections along the line.

Voltage Drop on Grounded Side

With a voltmeter on the 3 volt scale and without disconnecting any wires, connect negative test lead of the voltmeter to a prod secured in the ground-

ed battery post. The positive test lead is connected to a cleaned, bare metal portion of the starter motor housing. Close the starter switch and note the voltmeter reading. If the reading is the same as battery reading, the ground circuit is open somewhere between the battery and the starter. In many cases, the reading will be very small. The reading shown will indicate voltage drop (loss) between battery ground post and starter housing. The drop should not exceed 0.2 volts. If the voltage drop is above the specified amount, the next step is to isolate and correct the cause. It can be a bad cable or connection anywhere in the battery-to-starter ground circuit. A check of this type should progress along the various points of possible trouble between the battery ground post and the starter motor housing until the trouble spot has been located.

Voltage Drop on Battery Side

Bad starter cranking may result from poor connections or faulty components of the battery or hot phase of the starter motor circuit. To check this phase of the circuit, without disconnecting any wires, connect a lead of a voltmeter to a prod secured in the hot post of the battery and the other voltmeter lead to the field terminal of the starting motor. The meter should be set to the 16-20 volt scale. Before closing the starter switch, the voltmeter reading will be that of the battery. After closing the starter switch, change the selector on the voltmeter to the 3 volt scale. With a jumper wire between the relay battery terminal and the relay starter switch terminal, crank the engine. If the starting motor cranks the engine, the relay (solenoid) is operating.

While the engine is being cranked, watch the voltmeter. It should not register more than 0.5 volts. If more than this, check each part of the circuit for voltage drop to isolate the trouble, (high resistance).

Without disturbing the voltmeter-to-battery hook-up, move the free voltmeter lead to the battery terminal of the relay (solenoid) and crank the engine. The voltmeter should show no more than 0.1 volts.

If this reading is correct, move the same voltmeter lead to the starting motor terminal of the relay (solenoid). While the engine is being cranked, the voltmeter should show no more than 0.3 volts. If it does, the trouble lies in the relay.

If the reading is correct, the trouble is in the cable or connections between the relay and the starting motor.

DIAGNOSIS

Starter won't Crank Engine

1. Dead battery.
2. Open starter circuit, such as:
 - a. Broken or loose battery cables.
 - b. Inoperative starter motor solenoid.
 - c. Broken or loose wire from starter switch to solenoid.
 - d. Poor solenoid or starter ground.
 - e. Bad starter switch.
3. Defective starter internal circuit, such as:
 - a. Dirty or burnt commutator.
 - b. Stuck, worn or broken brushes.
 - c. Open or shorted armature.
 - d. Open or grounded fields.
4. Starter motor mechanical faults, such as:
 - a. Jammed armature end bearings.
 - b. Bad bearing, allowing armature to rub fields.
 - c. Bent shaft.
 - d. Broken starter housing.
 - e. Bad starter worm or drive mechanism.
 - f. Bad starter drive or flywheel driven gear.
5. Engine hard or impossible to crank such as:
 - a. Hydrostatic lock caused by water or other liquid in combustion chamber.
 - b. Crankshaft seizing in bearings.
 - c. Piston or ring seizing.
 - d. Bent or broken connecting rod.
 - e. Seizing of connecting rod bearing.
 - f. Flywheel jammed or broken.

Starter Spins Free, won't Engage

Sticking or broken drive mechanism.

CHRYSLER IMPORTS

Starter System

DIRECT DRIVE TYPE

Disassembly and Assembly

MITSUBISHI

1986

1. Position the assembly in the soft jawed vise. Disconnect the field coil wire from the solenoid terminal.
2. Remove the solenoid-to-starter screws and the solenoid.

1. Magnetic switch tightening screw
2. Front bracket
3. Washer
4. Snapping
5. Stopring
6. Overrunning clutch and pinion

Exploded view of the Mitsubishi direct drive starter — 1986 Chrysler

3. Remove the through bolts and the commutator end frame cover. Remove both brushes and the brush plate. Slide the field frame from the armature.

4. Remove the shift lever pivot bolt, the rubber gasket and plate.

5. Press the stop collar from the snapping and remove the snapping, stop collar and clutch.

6. Brushes that are worn less than $\frac{1}{2}$ the length of new brushes or oil soaked should be replaced; new brushes are $\frac{11}{16}$ in. long.

To Assemble:

7. Do not immerse the starter clutch unit in cleaning solvent; lubricant will be washed from inside the clutch.

8. Place the drive unit on the armature shaft and while holding the armature, rotate the pinion. The drive pinion should rotate smoothly in 1 direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred replace the unit.

9. To assemble, lubricate the bushings/splines and reverse the disassembly procedures.

10. Install the clutch, stop collar, lock ring and shaft fork on the armature.

11. Install the armature assembly

and shift fork in the drive end housing.

12. To complete the installation, reverse the removal procedures.

FORD

1987-90

1. Position the starter in a soft jawed vise.

2. Remove the field strap-to-solenoid nut and the field strap.

3. Remove the solenoid-to-drive end housing screws. Remove the solenoid from the housing by guiding it away from the drive end housing and the plunger.

4. Disconnect the plunger from the drive yoke. If shims are present between the solenoid and the starter, save them for reinstallation; the shims determine the starter pinion depth clearance.

5. Remove the starter housing through bolts. Separate the starter housing from the drive end housing.

6. Remove the rear cover-to-field frame screws, separate the strap grommet from the rear cover and remove the rear cover.

7. Using a small pry bar, lift the retaining springs and remove the brushes from their channels.

NOTE: Before removing the brush plate, remove the brushes from the plate; this will prevent possible damage to the brushes.

Exploded view of the Ford direct drive starter—1987-90 Chrysler

8. Note the position of the yoke and separate it from the drive pinion. Remove the armature and the drive pinion from the drive housing.

9. From the drive housing, remove the yoke, seal and washer.

NOTE: When removing the drive pinion, do not clamp it in a vise, for damage to the internal parts may occur.

10. Using a deep socket or equivalent, drive the armature collar towards the armature to expose the snapping. Remove the snapping from the armature's groove and slide the drive pinion from the armature.

11. Using an ohmmeter, check the each commutator-to-armature core for grounds; there should be no movement of the ohmmeter indicator. If the ohmmeter indicates a ground, replace the armature.

12. Inspect the commutator burn spots, scored surface and/or dirt. Us-

ing a set of V-blocks and a dial indicator, check the commutator runout. If the runout is greater than 0.002 in., refinish the commutator or replace the armature.

13. Using a micrometer, check the commutator's outer diameter; if it is less than 1.220 in., replace the armature.

NOTE: Never use emery cloth to clean the commutator face.

14. Inspect the depth of the insulating material between the commutator segments; it should be greater than 0.008 in. If necessary to undercut the insulating material, use a broken hacksaw blade and scrap the material to a depth of 0.020-0.031 in.

15. If the armature core shows signs of scuffing, the bushings are probably worn and need replacement.

16. Inspect the field coil for corrosion, insulation burnt/bare spots and/or deterioration; if necessary, replace the field coil housing assembly.

17. Using an ohmmeter, check the field strap connector-to-brushes for continuity; if there is no continuity, replace the field coil housing assembly.

18. Using an ohmmeter, check for continuity between the field strap connector and the field coil housing; if there is continuity, replace the field coil housing assembly. When performing this test, be certain the brushes and wires are not touching the housing.

19. Measure the brush lengths for wear, if they are near or beyond 0.453 in., replace the brushes.

20. To inspect the drive pinion, perform the following procedures:

a. Inspect the drive pinion teeth for excessive wear or milling. If either condition exists, the drive pinion and flywheel (manual) or flexplate (automatic) must be replaced.

b. To check the one-way clutch, try to turn the drive pinion in both directions; it should turn freely one-way and lock up the other way.

To Assemble:

21. Lubricate the armature splines with Lubriplate® 777 or equivalent. Install the drive pinion and the locking collar on the armature. Install the snapping and pull the collar over the snapping to secure it.

22. Using Lubriplate® 777 or equivalent, lubricate the shift fork and install it into the drive end housing. Engage the armature assembly into the drive end housing and couple the shift fork with the drive pinion.

23. Position the drive end housing into a soft jawed vise (nose down) and install the plug and seal into the housing recess.

24. Lower the field coil housing over the armature and seat it onto the drive end housing; position the housing so the field strap is on the solenoid side.

25. Install the washers onto the armature. Load the brushes into the brush plate holders. With the brushes pull all the way back in the holders, position the brush springs on the brush sides.

26. Install the brush plate over the commutator. Push the brushes toward the commutator until the springs snap onto the brush ends. Make sure the brush wires do not contact any metal parts.

27. Seat the field strap grommet and the rear cover. Install the through bolts and torque them to 55-75 ft. lbs. Install the solenoid and shims, if equipped.

28. To check the pinion depth, perform the following procedures:

a. If the field strap was connected to the solenoid terminal, disconnect it.

17 CHARGING AND STARTING IMPORT

b. Using a 12 volt battery, attach the negative (–) terminal to the solenoid's M-terminal and the positive (+) terminal to the solenoid's S-terminal; this will energize the solenoid.

NOTE: When energizing the solenoid, do not engage it for more than 20 seconds. Between each engagement, allow it to cool for at least 3 minutes.

c. Using a feeler gauge and the solenoid energized, check the drive pinion-to-collar gap; it should be 0.020–0.080 in. If necessary, add or subtract shims between the solenoid and drive end housing until the desired depth is achieved.

REDUCTION DRIVE TYPE

Disassembly and Assembly

MITSUBISHI

NOTE: Do not place the stator frame in a vise or strike it with a hammer for damage to the permanent magnets could occur.

1. Disconnect the coil wire from the solenoid.

2. Remove the solenoid-to-front end frame screws and the solenoid.

3. Loosen, do not remove the commutator shield-to-brush holder screws.

4. Remove the through bolts, the rubber retainer (under solenoid) and the coin washer.

NOTE: When removing the output shaft assembly, do not loose the armature shaft ball.

5. Remove the stator frame, the commutator shield and output shaft assembly as a unit. Separate the clutch fork from the output shaft assembly.

6. From the stator frame, pull the output shaft assembly forward, then, push the armature and commutator shield to the rearward.

7. Remove the commutator shield-to-brush holder plate screws and the shield; do not remove the brush holder assembly.

8. Using a 22mm socket, slide it up against the commutator, slide the brush holder assembly onto the socket and position the socket/brush holder assembly aside.

9. To disassemble the output shaft assembly, perform the following procedures:

a. Remove the rubber packing ring and the gears.

b. Using a 17mm socket, position it into the armature end of the driveshaft and position the assembly in the vertical position, resting on the socket.

c. Using a 12 point 14mm socket, position it against the stopring (on the clutch end). Using a hammer, strike the socket to unseat the stopring and expose the snapping.

d. Remove the socket, the snapping and the stopring from the driveshaft.

e. Using fine sandpaper, remove any burrs from the driveshaft. Remove the overrunning clutch.

10. Using compressed air or dry cloths, clean the armature, the stator frame, the overrunning clutch, the solenoid and the brush holder. Using mineral spirits, clean all other components.

11. Inspect the following parts for damage and replace, if necessary:

a. The stator frame and permanent magnets

b. The driveshaft bushing (armature side)

c. The planetary gear set and driveshaft

d. The starter motor bushing and bearing

e. The carbon brushes for cracks, distortion and wear below 0.354 in.

NOTE: When inspecting the brushes, do not remove the socket from the brush holder.

12. Using a growler and a hacksaw blade (placed on top of the armature), rotate the armature and check it for a shorted condition. If the hacksaw blade vibrates, a short exists; replace the armature.

13. Using a test light, place a lead on the armature's core and the other on each commutator segment, inspect the armature for a grounded condition. If a ground exists, the test light will turn ON; replace the armature.

14. Using a test light, place the leads

1. Screw
2. Magnetic switch
3. Screw
4. Screw
5. Rear bracket
6. Brush holder
7. Brush

15. Planetary gear
16. Lever
17. Snapping
18. Stopring
19. Overrunning clutch
20. Internal gear
21. Planetary gear holder
22. Front bracket

Exploded view of the Mitsubishi reduction drive starter—Chrysler

on the adjacent commutator segments. If the test light turns **ON** between any 2 segments, the armature is shorted and must be replaced.

15. Inspect the commutator out-of-round, if it is more than 0.001 in., reface it on a lathe.

To Assemble:

16. Using motor oil, lubricate the driveshaft and the overrunning clutch bushing. Using Lubriplate®, lubricate the overrunning clutch spiral cut splines.

17. Install the overrunning clutch on the driveshaft/planetary gear assembly, followed by the stopring and the snapring; sure to seat the snapring in the shaft groove and crimp the it with a pair of pliers.

18. Using a battery terminal puller, attach it to the driveshaft tip and press the stopring over the snapring.

NOTE: When installing the stopring, be careful not to scratch the driveshaft.

19. Install the clutch fork, with the assembled planetary gear set, lubricated with lithium grease, into the front end housing; make sure the locating lugs are properly seated in the front end housing.

20. Install the coin washer and the rubber fork retainer.

21. Install the rubber backing ring by placing the largest rubber lug at the top.

22. Install the brush holder onto the armature's commutator; make sure the brushes and brush holders are seated in the holder. Inspect the flex washer and install the commutator shield onto the armature. Install the brush holder screws but do not tighten them.

23. Install the armature assembly into the stator frame and seat the wire grommet into the frame.

24. Be sure the armature spline gear is seated in the planetary gear seat with the armature shaft ball in place. Seat the armature shaft in the shaft bushing bore; rotate the stator frame to align the tabs on the drive housing frame.

25. Install the through bolts and torque to 28 inch lbs. Torque the brush holder screws to 18 inch lbs.

26. To complete the assembly, reverse the disassembly procedures.

1. Magnetic switch lead
2. Solenoid switch assembly
3. Dust cover and snapring
4. Rear cover assembly

5. Brush holder assembly
6. Field coil assembly
7. Armature assembly with shift lever
8. Pinion stop clip
9. Pinion assembly

Exploded view of the Isuzu non-reduction drive starter—2.0L engine

jawed vise. Disconnect the field coil wire from the solenoid terminal.

2. Remove the solenoid mounting screws and work the solenoid from the shift fork. Remove the bearing cover, the armature shaft lock, the washer, the spring and the seal.

3. Remove the commutator end frame cover through bolts, the cover, the brushes and the brush plate.

4. Slide the field frame from over the armature. Remove the shift lever pivot bolt, the rubber gasket and the metal plate.

5. Remove the armature assembly and the shift lever from the drive end housing. Press the stop collar from the snapring, then remove the snapring, the stop collar and the clutch assembly.

6. If the brushes are worn more than ½ the length of new brushes or are oil-soaked, should be replaced; the new brushes are 0.630 in. long.

7. Do not immerse the starter clutch unit in cleaning solvent as the solvent will wash the lubricant from the clutch. Place the drive unit on the armature shaft, then, while holding the armature, rotate the pinion.

NOTE: The drive pinion should rotate smoothly in one direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function

properly or if the pinion is worn, chipped or burred, replace the unit.

To Assemble:

8. Lubricate the armature shaft and splines with lubricant.

9. Install the clutch, the stop collar, the lock ring and the shift fork onto the armature.

10. Install the armature assembly into the drive end housing.

11. Install the field frame housing over the armature and onto the drive end housing.

12. Position the brushes into the brush holder and position the brush holder over the armature's commutator.

13. Install the commutator end housing and the through bolts.

14. Install the cap end gasket, the armature brake spring, the armature plate and the commutator end cap.

ISUZU

Starting System

NON-REDUCTION TYPE

Disassembly and Assembly

1. Position the starter in a soft

REDUCTION GEAR TYPE

Disassembly and Assembly

1. Position the starter in a soft jawed vise. Remove the nut and disconnect the motor wire from the magnetic switch terminal.

2. Remove the through bolts and

Exploded view of the Isuzu reduction drive starter—2.3L engine

Exploded view of the Isuzu reduction drive starter—2.2L diesel engine

pull the field frame (with the armature) from the magnetic switch assembly.

3. Remove the starter housing to magnetic switch assembly bolts and separate the housing from the assembly. Remove the pinion gear, the pinion retainer/bearings and the clutch assembly.

4. Using a magnetic finger, remove the spring and the steel ball from the

hole in the clutch assembly shaft. Remove the field frame end cover.

5. Using a small pry bar, separate the brush springs, then remove the brushes from the brush holder and pull the brush holder from the field frame.

6. Remove the armature from the field frame. Using an ohmmeter, make sure there is no continuity between the commutator and the armature coil

core. If there is continuity, replace the armature.

7. Using an ohmmeter, check for continuity between the commutator segments. If there is no continuity between any of the segments, replace the armature.

8. If the commutator is dirty, burnt or the runout exceeds 0.002 in., use a lathe to reface the surface; do not machine the diameter to less than 1.140 in. diameter.

9. Using an ohmmeter, make sure there is continuity between the lead wire and the brush lead of the field coil. If there is no continuity, replace the field frame.

10. Using an ohmmeter, make sure there is no continuity between the field coil and the field frame. If there is continuity, replace the field frame.

11. If the brush length is less than 0.394 in., replace the brush and dress with emery cloth.

12. Check the gear teeth for wear or damage, if damaged, replace them. Turn the clutch assembly pinion clockwise and make sure it rotates freely, try to turn the pinion counterclockwise and make sure it locks. If the pinion does not respond correctly, replace it.

13. While applying inward force on the bearings, turn each by hand; if resistance or sticking is noticed, replace the bearings. To replace the bearings, use the tool 09286-46011 or equivalent, to pull the bearing(s) from the armature shaft. Using the tool 09285-76010 or equivalent, and an arbor press, press the new bearing(s) onto the armature shaft.

14. Using an ohmmeter, check for continuity between the grounded terminal and the insulated terminal, then between the grounded terminal and the housing. If there is no continuity in either case, replace the magnetic switch assembly.

To Assemble:

15. Lubricate the gears, the shafts and bearings with high temperature grease.

16. Install the over-running clutch, the pinion and the retainers with the rollers into the housing.

17. Install the spring to the magnetic switch and assembly the housing and the magnetic switch.

18. Install the brushes into the brush holder; make sure the positive brush leads are not grounded.

19. Install the rear end frame to the yoke, engage the tab with the wire grommet and install the cover.

20. Install the yoke to the magnetic switch, engage the tab on the yoke with the magnetic switch notch.

21. To complete the installation, reverse the removal procedures.

MAZDA

Starting System

NON-REDUCTION TYPE

Disassembly and Assembly

1. Remove the starter from the engine.
2. Disconnect the field strap from the solenoid.
3. Remove the screws attaching the solenoid to the drive end housing. Disengage the solenoid plunger hook from the shift fork and remove the solenoid.
4. Remove the shift fork pivot bolt, nut and lockwasher.
5. Remove the through bolts and separate the drive end housing from the starter frame. At the same time, disengage the shift fork from the drive assembly.
6. Remove the brush end bearing cover-to-brush end cover screws.
7. Remove the C-washer, washer and spring from the brush end of the armature shaft.
8. Pull the brush end cover from the starter frame.
9. Slide the armature from the starter frame and brushes.
10. Slide the drive stop-ring retainer toward the armature and remove the

stop-ring. Slide the retainer and drive assembly off the armature shaft.

11. Remove the field brushes from the brush holder and separate the brush holder from the starter frame.

To Assemble:

12. Position the drive assembly on the armature shaft.
13. Position the drive stop-ring retainer on the armature shaft and install the drive stop-ring. Slide the stop-ring retainer over the stop-ring to secure the stop-ring on the shaft.
14. Position the armature in the starter frame. Install the brush holder on the armature and starter frame. Install the brushes in the brush holder.
15. Install the drive end housing on the armature shaft and starter housing. Engage the shift fork with the starter drive assembly as the drive end housing is moved toward the starter frame.
16. Install the brush end cover on the starter frame making sure that the rear tabs of the brush holder are aligned with the through-bolt holes.
17. Install the through-bolts.
18. Install the rubber washer, spring, washer and C-washer on the armature shaft at the brush end. Install the brush end bearing cover on the brush end cover and install the attaching screws. If the brush end cover is not properly positioned, the bearing cover screws cannot be installed.

19. Align the shift fork with the pivot bolt hole and install the pivot bolt, lockwasher and nut. Tighten the nut securely.

20. Position the solenoid on the drive end housing. Be sure that the solenoid plunger hook is engaged with the shift fork.

21. Install both solenoid retaining screws and washers.

22. Apply 12 volts to the solenoid **S** terminal (ground the **M** terminal) and check the clearance between the starter drive and the stop-ring retainer. The clearance should be 0.080–0.200 in. If not, the solenoid plunger is not properly adjusted. The clearance can be adjusted by inserting an adjusting shim between the solenoid body and drive end housing.

23. Install the field strap and tighten the nut.

24. Install the starter. Check the operation of the starter.

COAXIAL REDUCTION TYPE

Disassembly and Assembly

1. Position the starter in a soft jawed vise. Disconnect the field coil wire from the solenoid terminal.

2. Remove the solenoid mounting screws and work the solenoid from the shift fork. Remove the bearing cover, the armature shaft lock, the washer, the spring and the seal.

3. Remove the commutator end frame cover through bolts, the cover, the brushes and the brush plate.

4. Slide the field frame from over the armature. Remove the shift lever pivot bolt, the rubber gasket and the metal plate.

5. Remove the armature assembly and the shift lever from the drive end housing. Press the stop collar from the snapping, then remove the snapping, the stop collar and the clutch assembly.

6. If the brushes are worn more than 1/2 the length of new brushes or are oil-soaked, should be replaced; the new brushes are 0.630 in. long.

7. Do not immerse the starter clutch unit in cleaning solvent as the solvent will wash the lubricant from the clutch. Place the drive unit on the armature shaft, then, while holding the armature, rotate the pinion.

NOTE: The drive pinion should rotate smoothly in one direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred, replace the unit.

| 7. Planetary gear | |

Exploded view of the Mazda coaxial reduction drive starter

To Assemble:

8. Lubricate the armature shaft and splines with lubricant.
9. Install the clutch, the stop collar, the lock ring and the shift fork onto the armature.
10. Install the armature assembly into the drive end housing.
11. Install the field frame housing over the armature and onto the drive end housing.
12. Position the brushes into the brush holder and position the brush holder over the armature's commutator.
13. Install the commutator end housing and the through bolts.
14. Install the cap end gasket, the armature brake spring, the armature plate and the commutator end cap.

NON-COAXIAL REDUCTION TYPE

Disassembly and Assembly

1. Remove the starter from the vehicle. Position the unit in a soft jawed vise.
2. Remove the field connector nut, the solenoid switch screws and the solenoid.
3. If equipped with shims between the solenoid and the drive end housing, retain these for installation purposes.
4. Remove the starter through bolts and the brush holder bolts. Remove the commutator end frame from the armature and bearing assembly. Remove the field frame assembly and the armature from the center housing.
5. Pry back each brush spring so that each brush can be backed away from the armature about 1/4 in. Release the spring to hold the brushes in

the backed out position, then remove the armature from the field frame and brush holder.

6. Remove the shaft cover-to-center housing screws and the shaft cover. Remove the C-shaped washer and plate. Remove the center housing bolts, the center housing shim and thrust washers.

7. Remove the reduction gear, the spring holder and the lever springs.

8. To remove the drive pinion, perform the following procedures:

- a. Using a 5/8 in. socket, slide it over the shaft against the stopper.
- b. Using the socket as a driving tool, tap it with a hammer to move the stopper off the ring.
- c. Remove the stopper and the drive pinion.

9. Remove the pinion shaft and the lever assembly. Note the direction of the lever and the lever holders.

10. Clean all parts in the proper cleaning solution. Inspect all parts for wear and damage; replace or repair defective components as required. Inspect all bearings for wear, roughness or dryness; replace damaged bearings with new ones.

11. Inspect the armature commutator. If the commutator is rough, it should be refinished on a lathe; do not turn the commutator to less than 1.480 in. outside diameter.

12. With the brush holder assembly still attached to the field frame, test the field coils for open. Using a test lamp, place a test lead on the field coil connector and the other test lead on the positive (+) brush.

13. The test light should turn ON. If the test light fails to light, the field coil is open; the field coil must be replaced. Repeat the test on the other positive brush.

14. To test the field coil for ground, place a test light lead on the field coil connector and the other lead on the field frame; the test light should stay OFF. If the test light turns ON, the field coils are grounded to the field frame assembly; the field frame must be replaced.

To Assemble:

15. To replace the brushes, remove the positive brushes from the brush holder, the brush holder and the negative brush assembly from the field frame.

16. Cut the old brush leads off of their mountings as close to brush connection point as possible. Solder the new brushes as required. Careful installation of the positive side is necessary to prevent grounding of the brush connection point having no insulation.

17. Reinstall the positive and negative brushes in the brush holder assembly and position the assembly in the starter housing.

18. In order to replace the drive end bearing, it will be necessary to press the bearing out of the drive end housing using a press. Replace the armature commutator end bearing and the armature drive end bearing.

19. To assemble, reverse the disassembly procedures. Be sure to check all parts for wear and damage; repair or replace defective parts.

20. If either the drive end housing, pinion shaft, reduction gear, shim washers or center housing were replaced, it will be necessary to check the endplay for the pinion shaft. Install the plate and C-shaped washer onto the end of the pinion shaft.

21. With the drive end housing mounted in a soft jawed vise, measure the endplay. Insert feeler gauge between C-washer and cover plate, pry the pinion shaft in the axial direction to check the endplay; it should be 0.004-0.020 in.

22. If the endplay is not correct, remove the plate, C-shaped washer, center bracket and add or remove the shim thrust washers to adjust the endplay and recheck.

NOTE: Shim thrust washers are available in 2 thicknesses 0.010 in. and 0.020 in.

23. When the starter has been disassembled or the solenoid switch has been replaced, it is necessary to check the pinion position. Pinion position must be correct to prevent the top of the lever from rubbing on the clutch collar during cranking.

24. Connect the positive lead of a 12 volt battery to the "S" terminal on the switch and momentarily connect the other to the starter frame. This will shift the pinion into cranking position

Exploded view of the Mazda non-coxial reduction drive starter

and will retain it until the battery is disconnected. Do not leave engaged more than 30 seconds at a time.

25. Using a dial indicator (with pinion engaged), push the pinion shaft back by hand and measure the amount of pinion shaft movement; the clearance should be 0.020-0.080 in.

26. If the amount does not fall within limits, adjust it by adding or removing the shims which are located between the switch and the front bracket; adding shims decreases the amount of the movement. Solenoid switch shims are available in 2 thicknesses 0.020 in. and 0.010 in.

MITSUBISHI

Starting System

DIRECT DRIVE TYPE

Disassembly and Assembly

1. Remove the wire connecting the starter solenoid to the starter.

2. Remove the starter solenoid-to-starter drive housing screws and the solenoid.

3. Remove both long through bolts from the rear of the starter and separate the armature yoke from the armature.

4. Carefully remove the armature and the starter drive engagement lever from the front bracket, noting the way they are positioned along with the attendant spring and spring retainer.

5. Loosen both screws and remove the rear bracket.

6. Tap the stopper ring at the end of the drive gear engagement shaft in towards the drive gear to expose the snapping. Remove the snapping.

7. Pull the stopper, drive gear and overrunning clutch from the end of the shaft.

8. Inspect the pinion and spline teeth for wear or damage. If the engagement teeth are damaged, visually check the flywheel ring gear through the starter hole to insure that it is not damaged. It will be necessary to turn the engine over by hand to completely inspect the ring gear.

9. Check the brushes for wear.

Their service limit length is 0.453 in. Replace if necessary.

To Assemble:

10. Install the spring retainer and spring on the armature shaft.

11. Install the overrunning clutch assembly on the armature shaft.

12. Fit the stopper ring with its open side facing out on the shaft.

13. Install a new snapping and, using a gear puller, pull the stopper ring into place over the snapping.

14. Fit the small washer on the front end of the armature shaft.

15. Fit the engagement lever into the overrunning clutch and refit the armature into the front housing.

16. Fit the engagement lever spring and spring retainer into place and slide the armature yoke over the armature. Position the yoke with the spring retainer cut-out space in line with the spring retainer.

NOTE: Make sure the brushes are seated on the commutator.

17. Replace the rear bracket and retainer screws.

18. Install the through bolts in the end of the yoke.

17 CHARGING AND STARTING IMPORT

Exploded view of the Mitsubishi direct drive starter

19. Refit the starter solenoid, fitting the plunger over the engagement lever. Install the screws and connect the wire running from the starter yoke to the starter solenoid.

REDUCTION DRIVE TYPE

1. Remove the wire connecting the starter solenoid to the starter.

2. Remove the solenoid screws, pull it out, unhook and disengage it from the engagement lever.

3. Remove the through bolts in the end of the starter and the bracket screws. Pull off the rear bracket.

NOTE: Since the conical spring washer is contained in the rear bracket, be sure to take it out.

4. Remove the yoke and brush holder assembly while pulling the brush upward.

5. Pull the armature assembly out of the mounting bracket.

6. In the side of the mounting bracket that the armature fits into, there is a small dust cap held by screws. Remove it and remove the snapring and washer under it.

7. Remove the remaining bolts in the mounting bracket and split the reduction case.

Exploded view of the Mitsubishi reduction drive starter

NOTE: Several washers will come out when the case is split. These adjust the endplay for the pinion shaft. Do not lose them.

8. Remove the reduction gear, lever and lever spring from the front bracket.

9. Using a brass drift or deep socket, knock the stopper ring on the end of the shaft in toward the pinion. Remove the snapping. Remove the stopper, pinion and pinion shaft assembly.

10. Remove the ball bearings at both ends of the armature.

NOTE: The ball bearings are pressed in the front bracket and are not replaceable. Replace them together with the bracket.

11. Inspect the pinion and spline teeth for wear or damage. If the engagement teeth are damaged, visually check the flywheel ring gear through the starter hole to insure that it is not damaged also. It will be necessary to turn the engine over by hand to completely inspect the ring gear.

12. Check the brushes for wear. Their service limit length is 0.453 in. Replace if necessary.

13. Assembly is the reverse of disassembly. Be sure to replace all adjusting and thrust washers. When replacing the rear bracket, fit the conical spring pinion washer with its convex side fac-

ing out. Make sure the brushes seat on the commutator.

NISSAN

Starting System

NON-REDUCTION GEAR TYPE

Disassembly and Assembly MITSUBISHI

1. Position the assembly in the soft jawed vise. Disconnect the field coil wire from the solenoid terminal.

2. Remove the solenoid-to-starter screws and the solenoid from the shifting fork.

3. Remove the through bolts and the commutator end frame cover. Remove the 2 brushes and the brush plate. Slide the field frame from the armature.

4. Remove the shift lever pivot bolt, the rubber gasket and plate.

5. Remove the snapping, the clutch assembly and the drive end housing from the armature.

6. Press the stop collar from the snapping and remove the snapping, stop collar and clutch.

7. Brushes that are worn less than $\frac{1}{2}$ the length of new brushes or oil soaked should be replaced; new brushes are $\frac{11}{16}$ in. long.

To Assemble:

8. Do not immerse the starter clutch unit in cleaning solvent; lubricant will be washed from inside the clutch.

9. Place the drive unit on the armature shaft and while holding the armature, rotate the pinion. The drive pinion should rotate smoothly in one direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred replace the unit.

10. To assemble, lubricate the bushings/splines and reverse the disassembly procedures.

11. Install the clutch, stop collar, lock ring and shaft fork on the armature.

12. Install the armature assembly and shift fork in the drive end housing. Check the endplay, it should be 0.002-0.021 in.

HITACHI

1. Support the starter in a soft jawed vise.

2. Remove the rear mounting bracket-to-starter nuts, the bracket and the plastic cap.

Exploded view of the Mitsubishi non-reduction drive starter—Nissan

17 CHARGING AND STARTING IMPORT

Exploded view of the Hitachi non-reduction drive starter with center bracket— Nissan

Exploded view of the Hitachi non-reduction drive starter without center bracket— Nissan

3. Disconnect the field wire from the solenoid.

4. Remove the solenoid-to-starter nuts and the solenoid.

5. From the end cover, remove the nuts, the through bolts and the end cover.

6. Using a pin punch at the drive end housing, drive the yoke axle pin from the housing.

7. At the positive brushes, move the brush spring clips to the side of the brushes and pull the brushes away from the armature. Carefully pull the field housing from the drive end housing.

8. Remove the pinion yoke and armature from the drive end housing.

9. Using a deep socket which fits over the armature shaft, tap the stop collar (driving it toward the armature) to expose the snapring. Remove the snapring from the groove and slide it from the shaft.

NOTE: When removing the snapring, be careful not to bend or distort it.

10. Remove the stop collar, the drive pinion and the support plate.

11. Using compressed air or a brush, clean the drive pinion, the drive end frame, the armature, the field coils

and the starter frame; all other parts can be cleaned in solvent.

12. Inspect the condition of the starter parts, perform the following procedures:

a. Check for broken wires or badly soldered connections.

b. Replace any bushings which are scored or badly worn.

c. If the armature's commutator more than 0.005 in. out of round, reface it on a lathe.

NOTE: Never use emery cloth to clean a commutator.

d. The drive pinion should be free of excessive wear or damage.

e. If the brushes are cracked, broken, distorted or worn to less than 0.314 in., replace them.

f. Using a growler and a hacksaw blade (placed on top of the armature), rotate the armature and check it for a shorted condition. If the hacksaw blade vibrates, a short exists; replace the armature.

g. Using a test light, place a lead on the armature's core and the other on each commutator segment, inspect the armature for a grounded condition. If a ground exists, the test light will turn **ON**; replace the armature.

h. Using a test light, check for

continuity between the positive brushes; if no continuity exists, replace the winding. Repeat this test for the negative windings.

i. Using a test light, place a lead on the coil housing and the other on each coil lead, make sure there is **NO** continuity; if continuity exists, replace the winding(s).

To Assemble:

13. Lubricate the necessary parts and place the support plate onto the armature, followed by the drive pinion and the stop collar. Carefully slide the snapring into the armature groove. Slide the stop collar over the snapring until it locks.

14. Position the armature and pinion yoke into the drive end housing. Install the pinion yoke axle pin.

15. Install the coil housing over the armature and onto the drive end housing. Position the brush holder onto the coil housing. Install the brushes and secure the brush springs.

16. Install the solenoid to the drive end housing. Position the field wire grommet to the coil housing and connect field wire to the solenoid.

17. Install the end cover to the coil housing and the install the through bolts/nuts. Install the armature brake assembly, the plastic cover and the mounting bracket.

Exploded view of the Mitsubishi reduction drive starter—Nissan Pick-Up and Pathfinder

Exploded view of the Mitsubishi reduction drive starter—Nissan Axxess

REDUCTION GEAR TYPE

Disassembly and Assembly

MITSUBISHI

NOTE: Do not place the stator frame in a vise or strike it with a hammer for damage to the permanent magnets could occur.

1. Disconnect the coil wire from the solenoid.
2. Remove the solenoid-to-front end frame screws and the solenoid.
3. Loosen, do not remove the commutator shield-to-brush holder screws.
4. Remove the through bolts, the rubber retainer (under solenoid) and the coin washer.

NOTE: When removing the output shaft assembly, do not loose the armature shaft ball.

5. Remove the stator frame, the commutator shield and output shaft assembly as a unit. Separate the clutch fork from the output shaft assembly.
6. From the stator frame, pull the output shaft assembly forward, then, push the armature and commutator shield to the rearward.
7. Remove the commutator shield-to-brush holder plate screws and the

shield; do not remove the brush holder assembly.

8. Using a 22mm socket, slide it up against the commutator, slide the brush holder assembly onto the socket and position the socket/brush holder assembly aside.

9. To disassemble the output shaft assembly, perform the following procedures:

- a. Remove the rubber packing ring and the gears.
- b. Using a 17mm socket, position it into the armature end of the driveshaft and position the assembly in the vertical position, resting on the socket.
- c. Using a 12 point 14mm socket, position it against the stopring (on the clutch end). Using a hammer, strike the socket to unseat the stopring and expose the snapping.
- d. Remove the socket, the snapping and the stopring from the driveshaft.
- e. Using fine sandpaper, remove any burrs from the driveshaft. Remove the overrunning clutch.

10. Using compressed air or dry cloths, clean the armature, the stator frame, the overrunning clutch, the solenoid and the brush holder. Using mineral spirits, clean all other components.

11. Inspect the following parts for damage and replace, if necessary:

- a. The stator frame and permanent magnets
- b. The driveshaft bushing (armature side)
- c. The planetary gear set and driveshaft
- d. The starter motor bushing and bearing
- e. The carbon brushes for cracks, distortion and wear below 0.354 in.

NOTE: When inspecting the brushes, do not remove the socket from the brush holder.

12. Using a growler and a hacksaw blade (placed on top of the armature), rotate the armature and check it for a shorted condition. If the hacksaw blade vibrates, a short exists; replace the armature.

13. Using a test light, place a lead on the armature's core and the other on each commutator segment, inspect the armature for a grounded condition. If a ground exists, the test light will turn ON; replace the armature.

14. Using a test light, place the leads on the adjacent commutator segments. If the test light turns ON between any 2 segments, the armature is shorted and must be replaced.

15. Inspect the commutator out-of-

round, if it is more than 0.001 in., re-face it on a lathe.

To Assemble:

16. Using motor oil, lubricate the driveshaft and the overrunning clutch bushing. Using Lubriplate®, lubricate the overrunning clutch spiral cut splines.

17. Install the overrunning clutch on the driveshaft/planetary gear assembly, followed by the stopring and the snapping; sure to seat the snapping in the shaft groove and crimp the it with a pair of pliers.

18. Using a battery terminal puller, attach it to the driveshaft tip and press the stopring over the snapping.

NOTE: When installing the stopring, be careful not to scratch the driveshaft.

19. Install the clutch fork, with the assembled planetary gear set, lubricated with lithium grease, into the front end housing; make sure the locating lugs are properly seated in the front end housing.

20. Install the coin washer and the rubber fork retainer.

21. Install the rubber backing ring by placing the largest rubber lug at the top.

22. Install the brush holder onto the armature's commutator; make sure the brushes and brush holders are

seated in the holder. Inspect the flex washer and install the commutator shield onto the armature. Install the brush holder screws but do not tighten them.

23. Install the armature assembly into the stator frame and seat the wire grommet into the frame.

24. Be sure the armature spline gear is seated in the planetary gear seat with the armature shaft ball in place. Seat the armature shaft in the shaft bushing bore; rotate the stator frame to align the tabs on the drive housing frame.

25. Install the through bolts and torque to 28 inch lbs. Torque the brush holder screws to 18 inch lbs.

26. To complete the assembly, reverse the disassembly procedures.

HITACHI

With Planetary Gears

1. Position the assembly in a soft jawed vise. Remove the field terminal nut, the terminal and the washer.

2. Remove the solenoid-to-starter screws. Work the solenoid from the shift fork and remove the solenoid from the starter.

3. Remove the starter end shield bushing cap screws, the starter end shield bushing-cap, the end shield bushing and C-washer.

4. Remove the starter end shield bushing washer and seal.

5. Remove the starter through bolts, the starter end shield and the brush plate.

6. Slide the field frame from the starter and over the armature. Remove the armature assembly from the drive end housing.

7. Remove the rubber seal from the drive end housing. Remove the starter drive gear train.

8. Remove the dust plate. Press the stop collar from the snapping. Using snapping pliers, loosen the snapping.

9. Remove the output shaft snapping, the clutch stopring collar and the clutch assembly from the starter.

10. Remove the clutch shift lever bushing, the clutch shift lever and the C-clip retainer.

11. Remove the retaining washer, the sun and the planetary gears from the annulus gear.

12. To assemble, lubricate the necessary parts and reverse the disassembly procedures. Replace all defective components as required.

Without Planetary Gears

1. Remove the starter from the vehicle. Position the unit in a soft jawed vise.

2. Remove the field coil screw, the

Exploded view of the Hitachi reduction drive starter with planetary gears - Nissan Pick-Up and Pathfinder

Exploded view of the Hitachi reduction drive starter with planetary gears—Nissan Axxess

field frame through bolts and separate the field frame assembly from the drive gear assembly. Separate the armature and the commutator end frame from the field frame.

3. Remove the solenoid screws and the solenoid from the drive housing.

4. Remove the retaining ring, shift lever shaft and housing through bolts. Separate the drive assembly, drive housing and gear assembly.

5. To remove the overrunning clutch from the armature shaft, perform the following procedures:

a. Remove the washer or collar from the armature shaft.

b. Using a $\frac{5}{8}$ in. deep socket, slide it over the shaft and against the retainer. Use the socket as a driving tool, tap the socket with a hammer to move the retainer off of the snapping.

c. Remove the snapping from the groove in the shaft; if the snapping is distorted, replace it.

d. Remove the retainer and the clutch assembly from the armature shaft.

6. To replace the starter brushes,

remove the brush holder pivot pin which positions the insulated and the ground brushes. Remove the brush spring.

7. Inspect armature commutator, shaft and bushings, overrunning clutch pinion, brushes and springs for discoloration, damage or wear; replace the damaged parts (if necessary). Check the armature shaft fit in drive housing bushing; the shaft should fit snugly in the bushing. If the bushing is worn, it should be replaced.

8. Inspect armature commutator. If commutator is rough, it should be re-finished on a lathe; do not undercut or turn to less than 1.650 in. O.D. Inspect the points where the armature conductors join the commutator bars to make sure they have a good connection. A burned commutator is usually evidence of a poor connection.

9. Using a growler and holding hacksaw blade over armature core while armature is rotated, check the armature for short circuits; if the saw blade vibrates, the armature is shorted.

10. Using a test lamp, place a lead on

the shunt coil terminal and the other lead to a ground brush. The test should be made from both ground brushes to insure continuity through both brushes and leads. If the lamp fails to light, the field coil is open and will require replacement.

11. Using a test lamp, place a lead on the series coil terminal and the other lead on the insulated brush. If the lamp fails to light, the series coil is open and will require repair or replacement. The test should be made from each insulated brush to check brush and lead continuity.

12. If equipped with a shunt coil, separate the series and shunt coil strap terminals during this test; do not allow the strap terminals to touch the case or other ground. Using a test lamp, place a lead on the grounded brush holder and the other lead on either insulated brush. If the lamp lights, a grounded series coil is indicated and must be repaired or replaced.

NOTE: If the solenoid has not been removed from the starter, the connector strap terminals

Exploded view of the Hitachi reduction drive starter with front mounted brush holder—Nissan

Exploded view of the Hitachi reduction drive starter with rear mounted brush holder—Nissan

17 CHARGING AND STARTING IMPORT

must be removed before making the following tests. Complete the tests as fast as possible in order to prevent overheating the solenoid.

13. To check the starter winding, connect an ammeter in series with a 12 volt battery, the switch terminal and to ground. Connect a carbon pile across the battery. Adjust the voltage to 10 volts and note the ammeter reading; it should be 14.5–16.5 amperes.

14. To check both windings, connect as for previous test. Ground the solenoid motor terminal, adjust the voltage to 10 volts and note the ammeter reading; it should be 41–47 amperes.

15. Current draw readings above specifications indicate shorted turns or a ground in the windings of the solenoid; the solenoid should be replaced. Current draw readings under specifications indicate excessive resistance. No reading indicates an open circuit. Check the connections and replace solenoid (if necessary). Current readings will decrease as windings heat up.

To Assemble:

16. The roller bearing in the drive housing and the roller bearings in the gear housing must be replaced (if they are dry); do not lubricate or reuse the bearings.

17. To replace the gear housing bearing, use a tube or solid cylinder that just fits inside the housing to push bearing toward the armature side. In the opposite direction, use the tube or cylinder to press bearing flush with housing.

18. To replace the gear housing driveshaft bearing, use a tube or collar that just fits inside the housing and press bearing out; press against the open end of bearing. To install a new bearing, press against the closed end, using a thin wall tube or collar that fits in space between bearing and housing. Do not press against the flat end of the bearing; this will bend the thin metal of the bearing. As required, replace the drive housing bearing.

19. To assemble, reverse the disassembly procedures. Be sure to replace or repair all defective components as required.

NOTE: When the starter has been disassembled or the solenoid replaced, it is necessary to check the pinion clearance. The pinion clearance must be checked in order to prevent the buttons on the shift lever yoke from rubbing on the clutch collar during engine cranking.

20. To check the pinion clearance, perform the following procedures:

a. Disconnect the motor field coil connector from the solenoid motor terminal and insulate the terminal.

Exploded view of the Suzuki starter

b. Connect the positive (+) 12 volt battery lead to the solenoid switch terminal and the other to the starter frame.

c. Touch a jumper lead momentarily from the solenoid motor terminal to the starter frame; this will shift the pinion into cranking position and retain it until the battery is disconnected.

d. Using a feeler gauge, push the pinion back as far as possible, to take up any movement, and check the clearance; the clearance should be 0.010–0.140 in.

e. Means for adjusting pinion clearance is not provided on the starter motor. If the clearance does not fall within limits, check for improper installation and replace worn parts.

of the field coil lead to the terminal on the head of the magnetic switch.

2. Remove the magnetic switch mounting screws and the switch from the motor body.

3. Loosen the bolts and screws and remove the commutator end cover.

4. Separate the drive housing and armature from the yoke.

5. Draw the brushes out of the holder.

6. Draw the stopring toward the clutch side and remove the armature ring and slide off the overrunning clutch.

7. To assemble, reverse the disassembly procedures. Replace brushes that are worn more than 0.450 in. New brushes are 0.670 in.

REDUCTION GEAR TYPE

Disassembly and Assembly

TRACKER

1. Position the starter in a soft jawed. Disconnect the field coil wire from the solenoid terminal.

2. Remove the solenoid mounting screws and work the solenoid from the shift fork. Remove the bearing cover, the armature shaft lock, the washer, the spring and the seal.

3. Remove the commutator end frame cover through bolts, the cover, the brushes and the brush plate.

4. Slide the field frame from over the armature. Remove the shift lever pivot bolt, the rubber gasket and the metal plate.

5. Remove the armature assembly and the shift lever from the drive end housing. Press the stop collar from the snapping, then remove the snapping, the stop collar and the clutch assembly.

6. If the brushes are worn more than $\frac{1}{2}$ the length of new brushes or are oil-soaked, should be replaced; the new brushes are 0.630 in. long.

7. Do not immerse the starter clutch unit in cleaning solvent as the solvent will wash the lubricant from the clutch. Place the drive unit on the armature shaft, then, while holding the armature, rotate the pinion.

NOTE: The drive pinion should rotate smoothly in one direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred, replace the unit.

To Assemble:

8. Lubricate the armature shaft and splines with lubricant.

9. Install the clutch, the stop collar, the lock ring and the shift fork onto the armature.

10. Install the armature assembly into the drive end housing.

11. Install the field frame housing over the armature and onto the drive end housing.

12. Position the brushes into the brush holder and position the brush holder over the armature's commutator.

13. Install the commutator end housing and the through bolts.

14. Install the cap end gasket, the armature brake spring, the armature plate and the commutator end cap.

TOYOTA

Starting System

REDUCTION DRIVE TYPE

Disassembly and Assembly

1. Position the assembly in a soft jawed vise. Remove the nut and disconnect the motor wire from the magnetic switch terminal.

2. Remove the through bolts and pull the field frame (with the armature) from the magnetic switch assembly.

3. On the 1.0 KW type, remove the

felt seal from the armature shaft; on the 1.4 KW type, remove the field frame to magnetic switch assembly O-ring.

4. Remove the starter housing to magnetic switch assembly bolts and separate the housing from the assembly.

5. On the 1.0 KW type, remove the idler gear and the clutch assembly. On the 1.4 KW type, remove the pinion gear, the idler gear and the clutch assembly.

6. Using a magnetic finger, remove the spring and the steel ball from the hole in the clutch assembly shaft.

7. Remove the field frame end cover. On the 1.4 KW type, remove the large O-ring.

8. Using a small pry bar, separate the brush springs, remove the brushes from the brush holder and pull the brush holder from the field frame. Remove the armature from the field frame.

9. Using an ohmmeter, make sure there is no continuity between the commutator and the armature coil core; if there is continuity, replace the armature.

10. Using an ohmmeter, check for continuity between the commutator segments. If there is no continuity between any of the segments, replace the armature.

11. If the commutator is dirty, burnt

17 CHARGING AND STARTING IMPORT

Exploded view of the 1.0 KW Nippondenso starter—Toyota

or the runout exceeds 0.0020 in., use a lathe to clean the surface; do not machine the diameter to less than 1.14 in. diameter.

12. Using an ohmmeter, make sure there is continuity between the lead wire and the brush lead of the field coil; if there is no continuity, replace the field frame.

13. Using an ohmmeter, make sure there is no continuity between the field coil and the field frame; if there is continuity, replace the field frame.

14. If the brush length is less than 0.335 in. (1.0 KW) or 0.394 in. (1.4 KW), replace the brush and dress with emery cloth.

15. Check the gear teeth for wear or damage, if damaged, replace them. Turn the clutch assembly pinion clockwise and make sure that it rotates freely, try to turn the pinion counter-clockwise and make sure that it locks. If the pinion does not respond correctly, replace it.

16. While applying inward force on the bearings, turn each by hand; if resistance or sticking is noticed, replace the bearings. To replace the bearings, use the tool 09286-46011 or equivalent, to pull the bearing(s) from the armature shaft. Using the tool 09285-76010 or equivalent, and an arbor press, press the new bearing(s) onto the armature shaft.

17. Using an ohmmeter, check for continuity between the grounded terminal and the insulated terminal, then between the grounded terminal and the housing. If there is no continuity in either case, replace the magnetic switch assembly.

18. To inspect the armature, perform the following procedures:

a. Using digital volt-ohmmeter, check for continuity between the commutator's segments and core; if there is continuity, replace the armature. Check for continuity between the commutator's segments and the shaft; if there is continuity, replace the armature.

b. Using a set of V-blocks and a dial micrometer, measure the commutator's runout; if the runout is more than 0.002 in. (0.05mm), lightly turn the commutator on a lathe. If the commutator's runout is excessive, replace the armature.

c. Using a micrometer, check the commutator's outer diameter; if it is less than 1.14 in. (29mm), replace the armature.

d. Using commutator sand paper, clean the commutator's face of burnt spots and/or scoring; do not use emery cloth.

e. If the depth between the commutator segments is less than 0.008 in. (0.2mm), use a broken hacksaw

blade to undercut the insulating material to 0.008-0.024 in. (0.2-0.6mm).

19. Inspect the armature bearing for looseness, binding or abnormal noise; if necessary, replace it.

20. Inspect the clutch/drive assembly gear teeth for wear, milling and/or chipping; if necessary, replace the assembly.

21. Inspect the pinion and idler gears for wear and/or damage; replace the gears if, necessary.

22. Inspect the brushes for wear by measuring the amount of useable brush remaining; the wear limit is 0.39 in. (10.0mm). Check the brushes for free movement in the brush holder; if necessary, clean the brush channels.

To Assemble:

23. Lubricate the gears, shafts and bearings with high temperature grease. Install the armature into the frame and field assembly.

24. Position the brushes into the brush holder.

25. Install a new O-ring onto the frame and field assembly.

26. Install the commutator end housing and screws.

27. Install the pinion gear, the idler gear bearing, the idler gear and the clutch/drive assembly; be sure to mesh the idler gear with the clutch and drive assembly during installation.

Exploded view of the 1.4 KW and 1.6 KW Nippondenso starters—Toyota

28. Install the spring into the solenoid assembly.

29. Install the drive housing to the solenoid screws.

30. Using a new O-ring, install it onto the drive housing side of the field frame assembly.

31. Align the matchmarks and install the field frame assembly onto the drive housing. Install and torque the through bolts to 33 ft. lbs. (45 Nm).

32. Install the lead wire to the starter solenoid terminal and torque the nut to 26 ft. lbs. (35 Nm).

2. Remove the solenoid-to-starter screws and the solenoid, for automatic transmissions, and work the solenoid plunger, for automatic transmissions, from the shifting fork.

3. Remove the end shield bearing cap screws, the cap and washers.

4. Remove the through bolts and the commutator end frame cover. Remove the 2 brushes and the brush plate. Slide the field frame from the armature.

5. Remove the shift lever pivot bolt, the rubber gasket and plate.

6. For the automatic transmission models, remove the armature assembly and shift lever from the drive end housing. For the manual transmission models, press the stop collar from the snapping. Remove the snapping, the clutch assembly and the drive end housing from the armature.

7. For the automatic transmission model, press the stop collar from the snapping and remove the snapping, stop collar and clutch.

8. Brushes that are worn less than $\frac{1}{2}$ the length of new brushes or oil soaked should be replaced; new brushes are $\frac{11}{16}$ in. long.

9. Do not immerse the starter clutch unit in cleaning solvent; lubricant will be washed from inside the clutch.

10. Place the drive unit on the armature shaft and while holding the armature, rotate the pinion. The drive pinion should rotate smoothly in 1 direction only. The pinion may not rotate easily but as long as it rotates smoothly it is in good condition. If the clutch unit does not function properly or if the pinion is worn, chipped or burred replace the unit.

11. To assemble, lubricate the bushings/splines and reverse the disassembly procedures.

12. On the automatic transmission models, install the clutch, stop collar, lock ring and shaft fork on the armature. On the manual transmission models, install the drive end housing on the armature, the clutch, stop collar and snapping on the armature.

13. On the automatic transmission models, install the armature assembly and shift fork in the drive end housing. Install the shim and armature shaft lock. Check the endplay, it should be 0.002–0.021 in.

DOMESTIC BRAKE SYSTEM SERVICE

HYDRAULIC BRAKE SYSTEM TROUBLE DIAGNOSIS

Condition	Possible Cause	Correction
Insufficient brakes	1. Improper brake adjustment. 2. Worn lining. 3. Sticking brakes. 4. Brake valve pressure low. 5. Master cylinder low on brake fluid.	1. Adjust brakes. 2. Replace brake lining and adjust brakes. 3. Lubricate brake pivots and support platforms. 4. Inspect for leaks and obstructed brake lines. 5. Fill master cylinder and inspect for leaks.
Brakes apply slowly	1. Improper brake adjustment or lack of lubrication. 2. Excessive leakage with brakes applied. 3. Restriction in brake line or hose.	1. Adjust brakes and lubricate linkage. 2. Inspect all fittings and lines for leaks and repair as necessary. 3. Clean or replace brake line or hose.
Spongy pedal	1. Air in hydraulic system. 2. Swollen rubber parts due to contaminated brake fluid. 3. Improper brake shoe adjustment. 4. Brake fluid with low boiling point. 5. Brake drums ground excessively.	1. Fill and bleed hydraulic system. 2. Clean hydraulic system and recondition wheel cylinders and master cylinder. 3. Adjust brakes. 4. Flush hydraulic system and refill with proper brake fluid. 5. Replace brake drums.
Erratic brakes	1. Linings soaked with grease or brake fluid. 2. Primary and secondary shoes mounted in wrong position.	1. Correct the leak and replace brake lining. 2. Match the primary and secondary shoes and mount in proper position.
Chattering brakes	1. Improper adjustment of brake shoes. 2. Loose front wheel bearings. 3. Hard spots in brake drums. 4. Out-of-round brake drums. 5. Grease or brake fluid on lining.	1. Adjust brakes. 2. Clean, pack and adjust wheel bearings. 3. Grind or replace brake drums. 4. Grind or replace brake drums. 5. Correct leak and replace brake lining.
Squealing brakes	1. Incorrect lining. 2. Distorted brakedrum. 3. Bent brake support plate. 4. Bent brake shoes. 5. Foreign material embedded in brake lining. 6. Dust or dirt in brake drum. 7. Shoes dragging on support plate. 8. Loose support plate. 9. Loose anchor bolts. 10. Loose lining on brake shoes or improperly ground lining.	1. Install correct lining. 2. Grind or replace brake drum. 3. Replace brake support plate. 4. Replace brake shoes. 5. Replace brake shoes. 6. Use compressed air and blow out drums and support plate and shoes. 7. Sand support plate platforms and lubricate. 8. Tighten support plate attaching nuts. 9. Tighten anchor bolts. 10. Replace brake shoes and cam-grind lining.
Brakes fading	1. Improper brake adjustment. 2. Improper brake lining. 3. Improper type of brake fluid. 4. Brake drums ground excessively.	1. Adjust brakes correctly. 2. Replace brake lining. 3. Drain, flush and refill hydraulic system. 4. Replace brake drums.

HYDRAULIC BRAKE SYSTEM TROUBLE DIAGNOSIS

Condition	Possible Cause	Correction
Dragging brakes	1. Improper brake adjustment. 2. Distorted cylinder cups. 3. Brake shoe seized on anchor bolt. 4. Broken brake shoe return spring. 5. Loose anchor bolt. 6. Distorted brake shoe. 7. Loose wheel bearings. 8. Obstruction in brake line. 9. Swollen cups in wheel cylinder or master cylinder. 10. Master cylinder linkage improperly adjusted.	1. Correct adjust brakes. 2. Recondition or replace cylinder. 3. Clean and lubricate anchor bolt. 4. Replace brake shoe return spring. 5. Adjust and tighten anchor bolt. 6. Replace defective brake shoes. 7. Lubricate and adjust wheel bearings. 8. Clean or replace brake line. 9. Recondition wheel or master cylinder. 10. Correctly adjust master cylinder linkage.
Hard pedal	1. Incorrect brake lining. 2. Incorrect brake adjustment. 3. Frozen brake pedal linkage. 4. Restricted brake line or hose.	1. Install matched brake lining. 2. Adjust brakes and check fluid. 3. Free up and lubricate brake linkage. 4. Clean out or replace brake line hose.
Wheel locks	1. Loose or torn brake lining. 2. Incorrect wheel bearing adjustment. 3. Wheel cylinder cups sticking. 4. Saturated brake lining.	1. Replace brake lining. 2. Clean, pack and adjust wheel bearings. 3. Recondition or replace the wheel cylinder. 4. Reline front, rear or all four brakes.
Brakes fade (high speed)	1. Improper brake adjustment. 2. Distorted or out of round brake drums. 3. Overheated brake drums. 4. Incorrect brake fluid (low boiling temperature). 5. Saturated brake lining.	1. Adjust brakes and check fluid. 2. Grind or replace the drums. 3. Inspect for dragging brakes. 4. Drain, flush and refill and bleed the hydraulic brake system. 5. Reline brakes as necessary.

General Information

Servicing the hydraulic brake system is chiefly a matter of adjustments, replacement of worn or damaged parts and correcting the damage caused by grit, dirt or contaminated brake fluid. Always make sure the brake system is clean and tightly sealed when a brake job is completed and that only approved heavy duty brake fluid is used.

Approved heavy duty brake fluid keeps the correct consistency throughout the widest temperature range, will not affect rubber parts, helps protect metal parts and assures long, trouble free brake operation.

Never use brake fluid from a container that has been used for any other liquid. Mineral oil, alcohol, antifreeze or cleaning solvents, even in very small quantities, will contaminate brake fluid. Contaminated brake fluid will cause piston cups and the valve(s) in the master cylinder to swell and deteriorate.

Brake fluid will also absorb moisture from the air. Over time, brake fluid stored for long periods, and fluid inside the brake system will be affected by this moisture. Rust, corrosion and pitting of system components result.

Some fleet managers change the brake fluid in their vehicles every year or two to avoid brake system problems caused by moisture.

Use extreme care when using brake fluid. It will damage painted surfaces.

The hydraulic braking system consists of a master cylinder, sometimes a power booster depending on application, hydraulic line and hoses, control valves and calipers and/or wheel cylinders. Newer models incorporate a computer controlled wheel antilock system. When the brake pedal is depressed, the master cylinder forces brake fluid to the calipers and/or cylinders. Sliding rubber seals contain the fluid and prevent leakage.

Return springs in the master cylinder help the brake pedal return to the unapplied position. Check valves, in most cases regulate the return flow of the fluid to the master cylinder. Other valves, such as the metering valve, proportioning valve, or combination valve, regulate the flow of fluid to the caliper/wheel cylinder, to achieve efficient braking.

Dual braking systems were introduced on many light trucks and vans during the late 1960's. The main difference is the use of a tandem master

cylinder which is essentially two master cylinders in one. Two separate pistons share one bore and two fluid reservoirs are built into one housing. Dual brake lines split the calipers and/or wheel cylinders into two groups, each actuated by its own, separate master cylinder piston. In the event of failure of one of the dual systems, the other should provide enough braking to safely stop the vehicle. The development of dual braking systems is an improvement over the older single systems where a leak anywhere would allow the fluid to escape resulting in loss of braking.

The dual system usually includes some type of warning light on the instrument panel, activated by a pressure differential valve. The valve reacts to loss of hydraulic pressure that might result from failure on either side of the system.

Vehicles are generally equipped with either a front/rear wheel split or a diagonally split system. On front/rear systems, the front wheels are connected to one circuit while the rear wheels are connected to the other circuit. These systems are the most popular ever since front disc brakes were introduced. Since a greater amount of

brake fluid is moved in a disc brake system, one chamber of the master cylinder feeds the front discs, while the other chamber feeds the rear wheel cylinders.

Diagonally split systems have diagonally opposite wheels connected to each circuit.

Because of the differences in pressure and the amount of fluid required to operate disc brakes and drum brakes, a control valve, often called a proportioning valve or combination valve is installed between the master cylinder and the rest of the system. This valve has several sections and functions.

The metering, or hold off section of the valve limits the pressure to the front disc brakes until a predetermined front input pressure is reached, enough to overcome the rear shoe retractor springs. There is generally no restriction to the inlet pressures below about 3 psi to allow for pressure equalization during the no apply periods.

Another section of the valve proportions, or measures out the outlet pressure to the rear brakes after a predetermined rear input pressure has been reached. This is done to prevent rear wheel lockup on vehicles with light rear wheel loads.

Yet another section of the valve is

Brake proportioning valve—typical

designed to constantly compare front and rear brake pressure from the master cylinder and will turn on a warning light in the event of a front or rear system malfunction. On some systems, after repairs are made, and the system properly bled, the valve will center itself and the warning lamp will shut off. On other systems, the switch will latch so the warning light will stay on until a repair is made, and the switch manually reset, generally be one or two firm brake applications.

These valves are also designed with a bypass feature which assures full system pressure to the rear brakes in the event of a front brake system malfunction, and full front pressure is retained in the event of a rear malfunction.

These valves are not to be disassembled for repair. Replace defective valves.

General Motors Corporation height sensing valve—typical

Most light trucks have some sort of height sensing valve. The vehicle braking force is distributed to the front and rear wheels as determined by either a light or heavy payload. The valve is usually mounted on the frame and a linkage connects the valve to a bracket mounted on the axle.

Adding suspension accessories or other equipment (such as load leveling kits, lift kits, extra springs, etc.) or making modifications that will change the distance between the axle and frame without changing the load will provide a false reading to the sensing valve. This could result in unsatisfactory brake performance which could result in an accident and possibly personal injury.

GM CORPORATION BRAKE DIAGNOSIS

DIAGNOSIS OF THE BRAKE SYSTEM

Problem	Possible Cause	Correction
Uneven brake action (brakes pull)	1. Incorrect tire pressure. 2. Front end out of alignment. 3. Loose suspension parts. 4. Worn out brake linings. 5. Incorrect lining material. 6. Malfunctioning caliper assembly. 7. Loose calipers. 8. Contaminated brake linings. 9. Malfunctioning rear brakes. 10. Leaking wheel or piston cylinder seal. 11. Restricted brake tubes or hoses. 12. Unmatched tires on the same axle.	1. Inflate evenly on both sides to specifications. 2. Check and align to specifications. 3. Check all the suspension mountings. 4. Replace with lining of the correct material. 5. Replace with linings of the correct material. 6. Check for frozen or sluggish pistons and the lubrication of the retainer bolts. Caliper should slide. 7. Check and torque. 8. Repair as necessary. Replace the linings in complete axle sets. 9. Check for inoperative self adjusters. Weak return springs. Leaking wheel cylinders. 10. Repair as necessary. 11. Check for collapsed rubber hoses or damaged lines. Repair as necessary. 12. Same style tires with about the same tread should be used on the same axle.
Slow pedal return	Compensating (peripheral) holes in the quick take-up valve are clogged.	Replace the master cylinder.

DIAGNOSIS OF THE BRAKE SYSTEM

Problem	Possible Cause	Correction
Brakes squeak	1. Worn out linings. 2. Glazed brake linings. 3. Heat spotted rotors or drums. 4. Weak or incorrect brake shoe retention springs. 5. Contaminated brake linings. 6. Incorrect lining material. 7. Brake assembly attachments missing or loose. 8. Excessive brake lining dust.	1. Replace the linings. 2. Replace the linings. 3. Check per instructions. If within specifications, machine the rotor or drum. 4. Replace with new retention springs. 5. Repair as necessary. Replace the linings in complete axle sets. 6. Replace with linings of correct material. 7. Repair as necessary. 8. Clean the dust from the brake assembly.
Brake pedal pulsates	1. Excessive rotor lateral runout. 2. Rear drums out of round. 3. Heat spotted rotors or drums. 4. Incorrect wheel bearing adjustments. 5. Out of balance wheel assembly. 6. Brake assembly attachments missing or loose.	1. Check per instructions. If within specifications, machine the rotor. 2. Check per instructions. If within specifications, machine the drum. 3. Check per instructions. If within specifications, machine the drum. 4. Repair as necessary. 5. Repair as necessary. 6. Repair as necessary.
Excessive pedal effort	1. Leaking vacuum system. 2. Malfunctioning power brake unit. 3. Worn out linings. 4. Malfunctioning proportioning valve. 5. Incorrect lining material. 6. Incorrect wheel cylinder. 7. Center orifice in quick take-up valve clogged.	1. Repair as necessary. 2. Repair as necessary. 3. Replace the linings. 4. Replace the combination valve. 5. Replace with linings of the correct materials. 6. Replace with the correct size wheel cylinder. 7. Replace the master cylinder.
Brakes drag	1. Malfunctioning caliper assembly. 2. Contaminated or improper brake fluid. 3. Improperly adjusted parking brake. 4. Restricted brake tube or hoses. 5. Malfunctioning proportioning valve. 6. Malfunctioning self adjusters. 7. Malfunctioning master cylinder. 8. Improperly adjusted master cylinder pushrod.	1. Check for frozen or sluggish pistons and the lubrication of the retainer bolts. Caliper should slide. 2. Repair as necessary. 3. Adjust as necessary. 4. Check for collapsed rubber hoses or damaged lines. Repair as necessary. 5. Replace the combination valve. 6. Repair as necessary. 7. Repair as necessary. 8. Adjust pushrod length.

General Diagnosis

LOW PEDAL

Normal brake lining wear reduces pedal reserve. Low pedal reserve may also be caused by the lack of brake fluid in the master cylinder. This means a brake adjustment is required. Check fluid level in the master cylinder and add as required.

FLUID LOSS

If the master cylinder requires constant addition of brake fluid, fluid may be leaking past the piston cups in the master cylinder, calipers or wheel cylinders, the brake lines or hoses, or through loose connections. Brake hoses often have copper sealing washers which may need to be replaced. Replace worn or damaged components, refill and bleed the system.

FLUID CONTAMINATION

To determine if contamination exists in the brake fluid as indicated by swollen, deteriorated rubber parts like wheel cylinder cups, the following tests can be made.

Place a small amount of the drained brake fluid into a clear glass bottle. Separation of the fluid into distinct layers will indicate mineral oil content. Be safe and discard the old brake fluid that has been bled from the system since it may contain dirt and other contamination and should not be reused.

BRAKE ADJUSTMENT

Self adjusting brakes usually do not require manual adjustment. When installing new brake shoes, it may be advisable to make the initial adjustment manually to speed up adjusting time.

AUTOMATIC ADJUSTER CHECK

On most vehicles, drum brakes appear only on the rear axle. Brake adjustments are automatic and are made during reverse brake applications.

Raise and safely support the vehicle, have a helper in the driver's seat to apply brakes. Remove the plug from the adjustment slot to observe the star wheel (some models are adjusted through the face of the brake drum others through the backing plate). Tighten the adjusting star wheel screw until the wheel can just be turned by hand. The brake drag should be equal at both wheels. Back off the adjusting star wheel about 30-35 notches. The brakes should have no drag after the adjuster has been backed off about 15 notches. If heavy drag is present, the parking brake likely needs service and/or adjustment.

Brake adjustment—typical

NOTE: It will be necessary to carefully insert a small, stiff wire or thin tool to hold the automatic adjustment lever away from the star wheel to allow backing off the adjustment. Install adjusting hole cover in backing plate. Check parking brake adjustment.

HYDRAULIC LINE REPAIR

Steel tubing is used for the hydraulic lines, and special flexible hoses connect moving parts such as front calipers which turn with the steering, and the connection between the body and rear axle.

When replacing steel lines or flexible brake hose, use only exact replacements, in both size and quality.

NOTE: Never use copper tubing for hydraulic brake lines because copper is subject to fatigue cracking and corrosion which could result in brake failure. Use specially made steel brake lines only. Tighten all connections securely.

After replacement, bleed the brake system at each wheel and at the booster, if equipped with a bleeder screw.

Flexible hoses should be inspected for any signs of road damage, cracks or chafing any of which requires immediate hose replacement. Hoses feeding front brake calipers are often equipped with a copper washer for a seal. This should also be replaced when hoses are renewed. After hose installation, make sure the hose is not twisted. Many hoses have a painted stripe on them to help the technician determine if the hose is twisted.

If a length of steel brake line tubing must be replaced and the end flared, a special double flaring tool must be used. Always inspect newly formed flares for defects. Double lap flaring tools must be used. Single flares cannot hold the high pressures in the brake system and tend to crack. When bending brake tubing to fit the frame or rear axle contours, be careful not to

crack or kink the tube. Always clean the inside of even new brake tube with clean isopropyl alcohol.

GENERAL MOTORS CORPORATION

Master Cylinder Service

In addition to standard master cylinder functions, a quick take-up feature is included on most models. This provides a large volume of fluid to the wheels at low pressure with the initial brake application. This large volume of fluid is needed to overcome the clearance created by the seals retracting the pistons into the front calipers and the spring retraction of the rear brake shoes.

NOTE: General Motors Corporation does not recommend honing the bores of either cast iron or composite master cylinders. When the brake master cylinder is overhauled, it is recommended that the cylinder body be replaced rather than attempting to clean up a scuffed cylinder by honing the bore. The master cylinder has a hard, highly polished surface which is produced by diamond boring followed by ball or roller burnishing under heavy pressure. Honing will destroy this surface which will cause rapid wear of rubber cups. Do not use kerosene, gasoline or other solvents for cleaning or flushing master cylinder and components. The use of these solvents or any other with a trace of mineral oil, will damage rubber parts.

DELCO CAST IRON MASTER CYLINDER

Disassembly and Assembly

1. Remove cover, rubber diaphragm and drain reservoir.
2. Remove snapping and primary piston assembly.
3. Plug rear port and apply low pressure air to front port. Secondary piston will pop out. Use shop cloth to catch piston. Use caution. The piston may come out with considerable force. Remove seals from secondary piston.
4. If tube seats must be replaced,

GM cast iron master cylinder

thread in self-tapping screw into seat, remove with locking pliers.

5. Clean all metal parts in denatured alcohol, the rubber parts in brake fluid.

6. A stained or discolored bore may be cleaned with fine crocus cloth. Do not attempt to hone the bore.

7. Lube all seals and the bore with clean brake fluid. Install seals on pistons and assemble.

8. Push primary piston with smooth rounded end tool and install snapping.

9. If tube seats are replaced, seat with spare brake tube nut.

10. Install diaphragm into cover and install cover.

BENDIX MASTER CYLINDER

Disassembly and Assembly

1. Remove cover, rubber diaphragm and drain reservoir.
2. Locate and remove the reservoir to body bolts and remove reservoir.
3. Remove the seals, poppet valves and springs from cylinder body.
4. Remove snapping and primary piston.
5. Plug rear port and apply low pressure air to front port. Secondary piston will pop out. Use shop cloth to catch piston. Use caution. The piston may come out with considerable force. Remove seals from secondary piston.
6. Clean all metal parts in denatured alcohol, the rubber parts in brake fluid.
7. A stained or discolored bore may be cleaned with fine crocus cloth. Do not attempt to hone the bore.
8. Lube all seals and the bore with clean brake fluid. Install seals on pistons and assemble.
9. Push primary piston with smooth rounded end tool and install snapping.

Bendix master cylinder

10. Install O-ring, springs, valve poppets and compensating valve seals.

11. Bolt on reservoir, replace diaphragm and cover.

DELCO COMPOSITE MASTER CYLINDER

Disassembly and Assembly

EXCEPT LUMINA APV, SILHOUETTE AND TRANS SPORT

1. Remove cover, rubber diaphragm and drain reservoir.

2. Clamp mounting flange of cylinder in vise and pry reservoir off. Remove reservoir grommet.

3. Remove snapping and primary piston.

4. Plug rear port and apply low pressure air to front port. Secondary piston will pop out. Use shop cloth to catch piston. Use caution. The piston may come out with considerable force. Remove seals from secondary piston.

5. Clean all metal parts in denatured alcohol, the rubber parts in brake fluid.

6. A stained or discolored bore may be cleaned with fine crocus cloth. Do not attempt to hone the bore.

7. Lube all seals and the bore with clean brake fluid. Install seals on pistons and assemble.

8. Push primary piston with smooth rounded end tool and install snapping.

9. Install grommets and press reservoir on with rocking motion. Install diaphragm and cover.

LUMINA APV, SILHOUETTE AND TRANS SPORT

1. Remove cover, rubber diaphragm and drain reservoir.

2. Remove fluid level sensor switch using needle nose pliers to compress switch locking tabs at the inboard side of master cylinder.

3. Remove proportioner valve assemblies by unscrewing cap assemblies, removing the O-rings and

GM composite master cylinder

springs. Remove pistons with needle nose pliers. Use care. Do not scratch piston stems.

3. Remove snapping and primary piston.

4. Apply low pressure air into upper outlet port at blind end of bore. Plug all other ports. Secondary piston will pop out. Use shop cloth to catch piston. Use caution. The piston may come out with considerable force. Remove seals from secondary piston.

5. To remove reservoir, clamp flange (never the body) of master cylinder in vise. Drive out spring pins with 1/8 in. punch. Pull reservoir straight up and remove O-rings from grooves in reservoir.

6. Clean all metal parts in denatured alcohol, the rubber parts in brake fluid.

7. Inspect the bore for scoring or corrosion. If noted, replace master cylinder. No abrasives should be used in bore. Do not attempt to hone the bore.

8. Install new seals on reservoir, press into cylinder body and install spring pins.

9. Lube all seals and the bore with clean brake fluid. Install seals on pistons and assemble.

10. Push primary piston with smooth rounded end tool and install snapping.

11. Install proportioner valve assemblies and fluid level sensor, making sure locking tabs snap into place.

12. Install diaphragm and cover.

Brake Booster Service

Three types of brake boosters are used: a single diaphragm, a tandem diaphragm and a hydraulic booster (Hydro-Boost).

The vacuum boosters may have a vacuum switch to activate a brake warning light in case of low booster vacuum or vacuum pump malfunction.

Lumina APV master cylinder

tion. Under normal operating conditions, with brakes released, a vacuum suspended booster operates with vacuum on both sides of its diaphragm (or both diaphragms in a tandem diaphragm unit). When the brakes are applied, air at atmospheric pressure is admitted to one side of the diaphragm (or both diaphragms in a tandem diaphragm unit) to provide the power assist.

The hydraulic brake booster (Hydro-Boost) uses a hydraulic pump to power the system and a pneumatic accumulator as a reserve system. In this system no special fluids are used. However, care must be taken to use the correct fluids. The master cylinder and brake system operate on standard brake fluid. The hydraulic pump, which is driven by pressure from the power steering pump, uses power steering fluid.

VACUUM DIAPHRAGM BRAKE BOOSTERS

Disassembly and Assembly

SINGLE DIAPHRAGM BOOSTER

NOTE: A special brake booster disassembly tool is recommended for this procedure.

1. With the booster unit off the vehicle, and the master cylinder removed from the booster, take off the boot and silencer disc from the booster's mounting (rear) side. Remove the vacuum check valve, grommet and the front housing seal from the face side.

2. Scribe a mark across the front and rear housings to aid assembly.

3. Clamp the base in a vise with the power section facing up. Separate the front and rear housings by pressing down (using the special disassembly

GM Single Diaphragm Booster

Special tool presses down while housing is turned

tool, if available) and rotating the housing counterclockwise to the unlocked position. Loosen carefully as it is spring loaded.

4. Remove the large return spring and the power piston which will likely still have the pedal pushrod attached.

5. Remove the power piston bearing from the rear housing.

6. Remove the reaction body retainer, the master cylinder piston rod, and reaction retainer.

7. Remove the filter with an awl or similar tool.

8. Separate the power piston and pedal pushrod. To do this, grasp the outside edge of the diaphragm support and diaphragm. Hold the pushrod down against a hard surface and use slight force to dislodge the diaphragm retainer.

9. Remove the diaphragm from the diaphragm support.

10. Inspect all parts for corrosion, nicks, cracks, cuts, scoring, distortion or excessive wear. Replace as required. Clean all parts in denatured alcohol, but do not immerse the power piston and pushrod assembly in alcohol. Dry with compressed air.

11. Lubricate the inside diameter of the diaphragm lip with a thin layer of silicone grease and install the diaphragm into its support.

12. Install the diaphragm and support onto the power piston and push-

rod assembly. Use a new retainer and install with a pipe-like driver.

13. Install filter, reaction retainer, piston rod, and reaction body retainer.

14. Install the reaction body retainer disc. Lubricate the inside and outside of the power piston bearing with silicone grease and install in rear housing.

15. Install power piston group into rear housing, put in the return spring and assemble front housing to rear housing. Align mating marks made before disassembly.

16. Apply pressure in clockwise direction to lock housings together. Stake the housing at two tabs 180 degrees apart. Do not stake a tab that has been previously staked.

17. Lubricate the check valve grommet with silicone grease and install it and the check valve in the front cover.

18. Install the front housing seal, silencer disc, and boot.

19. The piston rod should be checked with a special GO, NO-GO gauge. If not within limits, replace the rod.

TANDEM DIAPHRAGM BOOSTER

NOTE: A special brake booster disassembly tool is recommended for this procedure.

1. With the booster unit off the vehicle, and the master cylinder removed from the booster, take off the boot and silencer disc from the booster's mounting (rear) side. Remove the vacuum check valve, grommet and the front housing seal from the face side.

2. Scribe a mark across the front and rear housings to aid assembly.

3. Clamp the base in a vise with the power section facing up. Separate the front and rear housings by pressing down (using the special disassembly tool, if available) and rotating the housing counterclockwise to the un-

Installing diaphragm retainer with pipe driver

Using special GO NO-GO gauge to check pushrod

Staking the booster tabs

locked position. Loosen carefully as it is spring loaded.

4. Remove the large return spring and the power piston which will likely still have the pedal pushrod attached.

5. Remove the power piston bearing from the rear housing.

6. Remove the piston rod, reaction retainer and power head silencer ring.

7. Remove the power piston assembly and pushrod. Grasp the assembly at the outside edge of the housing divider and both diaphragms. Hold the pushrod down against a hard surface. Tap to dislodge diaphragm retainer.

8. Remove the primary diaphragm (rear) and primary support plate from the housing divider and separate the primary diaphragm from its support plate.

9. Remove the secondary diaphragm (front) and secondary support plate from the housing divider. Remove the secondary piston bearing from the center of the housing divider and separate the secondary diaphragm from its support plate.

10. Remove the reaction plate retainer, reaction body, reaction disc, and reaction piston from the reaction body.

1. Boot
2. Silencer

28. Retaining Ring
29. Filter
30. Retainer
31. O-Ring
32. Air Valve Push Rod Assembly
33. Power Piston

Tandem diaphragm vacuum booster components

11. Remove the air valve spring and reaction bumper from the end of the pushrod. Carefully remove the retaining ring from the pushrod, and remove the pushrod by inserting a suitable tool through the eyelet end and pulling straight out. Considerable force will be required.

12. Remove the filter, retainer and O-ring from the pushrod assembly.

13. Inspect all parts for corrosion, nicks, cracks, cuts, scoring, distortion or excessive wear. Replace as required. Clean all parts in denatured alcohol, but do not immerse the power piston and pushrod assembly in alcohol. Dry with compressed air.

14. Using silicone grease, lubricate the O-ring for the pushrod and install the pushrod into the power piston, then install the retainer and seat.

15. Install the filter over the pushrod eyelet and into the power piston and install the retaining ring.

16. Assemble the reaction bumper, air valve spring, reaction piston and reaction disc into the reaction body. Install the reaction body retainer.

17. Using silicone grease, lubricate the inside diameter of both the primary and secondary diaphragm as well as the secondary piston bearing.

18. Assemble the secondary diaphragm to its support plate and slide the assembly over the power piston/pushrod assembly.

19. Install the secondary piston bearing into the housing divider. The flat surface of the bearing goes on the same side as the six raised lugs on the divider. Install this assembly over the power piston/pushrod assembly.

20. Assemble the primary diaphragm to its support plate, by folding the diaphragm up, away from the support plate and slide the assembly over the power piston/pushrod assembly. Fold the primary diaphragm back into position and pull the outside edge of the diaphragm over the formed flange of the housing divider.

NOTE: Check that the beads on the secondary diaphragm are seated evenly around the complete circumference.

21. Install a new diaphragm retainer and install with a pipe-like driver.

22. Install the silencer ring, reaction retainer and piston rod.

23. Lubricate the inside and outside diameters of the primary piston bearing with silicone grease and install into the rear housing.

24. Install the power piston assembly into the rear housing.

25. Install the return spring and assemble front housing to rear housing. Align mating marks made before disassembly.

26. Apply pressure in clockwise direction to lock housings together. Stake the housing at two tabs 180 degrees apart. Do not stake a tab that has been previously staked.

27. Lubricate the check valve grommet with silicone grease and install it and the check valve in the front cover.

28. Install the front housing seal, silencer disc, and boot.

29. The piston rod should be checked with a special GO, NO-GO gauge. If not within limits, replace the rod.

Hydro-Boost components

HYDRO-BOOST

The Bendix Hydro-Boost uses the hydraulic pressure supplied by the power steering pump to provide a power assist to brake application. It has identifying information stamped into the housing near the inlet line. When servicing this unit, there are some special tools that are recommended for these procedures.

Disassembly and Assembly

CAUTION

This system uses an accumulator that contains compressed gas. Do not apply heat to the accumulator. Use caution or personal injury may result. Do not attempt to repair a defective accumulator. Always replace with a new unit. Dispose of an inoperative accumulator by drilling a 1/16 in. diameter hole through the end of the accumulator can opposite the O-ring.

1. Remove the accumulator. Note that an adapter (a piece of strap metal with a hole drilled to accommodate a mounting stud) is used along with a C-clamp. Depress the accumulator with the C-clamp, insert a punch into the hole on the housing and remove the snapping retainer. Release the C-clamp, remove the accumulator and O-ring.

2. Remove the retainer from the small port above the mounting flange and remove the plug, O-ring and spring.

3. Remove the star-shaped retainer from the mounting flange bore and remove the output pushrod, baffle, piston return spring and inner retainer.

4. Remove the pedal rod boot and mounting bracket, if installed. On some installations it may be necessary to saw off the eyelet of the pedal rod. Make sure exact replacements or the replacement parts kit is available before cutting the original part.

5. Remove the cover bolts and separate the cover from the housing. Remove the seals (a large figure-eight shaped seal and a smaller seal on the end of the piston assembly).

6. Remove the piston assembly and the O-ring seal on the housing side of the piston.

7. Remove the spool valve.

8. Remove the accumulator valve. It may be necessary to fish this small valve out with a thin wire hook.

9. Remove the return line fitting and seal.

10. Clean all parts in power steering fluid. Inspect the spool valve for corrosion, nicks and scoring. If found, replace the complete booster. Discoloration of the spool or bore is not harmful and is no cause for replacement. Check all components for damage or wear, especially the tube seat in the housing. This seat can be removed with a Easy-Out type remover, and its replacement installed by tapping gently into place.

11. Lubricate all seals and friction

A. Nut
B. C-clamp
Removing the accumulator

Hydro-Boost seal leak areas

metal parts with power steering fluid.

12. Install the return line fitting and seal.

13. Install the accumulator valve and spool valve.

14. Install the seal and piston assembly, place the small seal on the piston assembly end and the figure eight

shaped seal into the housing. Install the cover and torque the bolts to 22 ft. lbs.

15. Install the mounting bracket and pushrod boot.

16. On the master cylinder side of the unit, install the output pushrod, baffle, piston return spring and retainer.

17. Install the accumulator and O-ring using a large C-clamp as in disassembly procedure.

18. Install the jam nut from the repair kit onto the pedal rod and install the eyelet onto the pedal rod.

Combination Valve

The combination valve (also called a proportioning valve) is made up of 3 sections, each serving a different function.

The metering or hold-off section of the valve limits the pressure to the front disc brakes until a predetermined front input pressure is reached, enough to overcome the rear shoe retractor springs. There is no restriction to the inlet pressures below 3 psi to allow for pressure equalization during no-apply periods.

The proportioning section of the combination valve proportions outlet pressure to the rear brakes after a predetermined rear input pressure has been reached. This is done to prevent rear wheel lockup on vehicles with light rear wheel loads.

The valve is designed to have a bypass feature which ensures full system pressure to the rear brakes in the event of a front brake system malfunction. Full front pressure is retained in the event of rear malfunction.

The pressure-differential warning switch is designed to constantly compare front and rear brake pressure from the master cylinder and energize the warning lamp on the instrument panel in the event of a front or rear system malfunction. The valve and switch are designed so the switch will latch in the warning position once a malfunction has occurred. The only way the lamp can be turned off is to repair the malfunction and apply a pedal force required to develop about 450 psi line pressure (a firm brake application).

Valve Overhaul

The combination valve is not repairable and must be replaced as a complete assembly.

Caliper Service

The disc brake assembly consists of a caliper and piston assembly, rotor, lin-

ings, and an anchor plate. The caliper is mounted to the anchor plate, which allows the caliper to move laterally against the rotor. The caliper is a one-piece casting with the inboard side containing the piston bore. A square cut rubber seal is located in a groove in the piston bore which provides the hydraulic seal between the piston and the cylinder wall.

As the brake pedal is pressed, hydraulic pressure is applied against the piston. This pressure pushes the inboard brake lining against the inboard braking surface of the rotor. As the force increases against the rotor, the caliper assembly moves inboard and provides a clamping action on the rotor.

When brake pressure is released, the piston seal returns to its normal position, pulling the piston back into the caliper bore. This creates a running clearance between the inner brake lining and rotor.

Disassembly and Assembly

1. Drain all fluid from caliper.

2. Pad interior of caliper with clean shop towels and use just enough compressed air to ease the piston out of the bore.

CAUTION

Do not place fingers in front of piston to try to catch piston or protect it when applying compressed air. This could result in serious injury. Use just enough air to ease the piston out. If piston is blown out, even with padding, it may be damaged.

3. Remove boot, being careful not to scratch bore.

4. Remove square cut seal from caliper bore groove.

5. Remove bleeder valve.

6. Clean all parts with denatured alcohol, blow dry with compressed air. Inspect all parts for scoring, corrosion or damage to chrome plating on piston. Replace if damaged. Fine crocus cloth can be used to polish out any light corrosion.

7. Lubricate the new piston seal, caliper bore and piston with clean brake fluid and install the seal in the

caliper bore groove. Make sure seal is not twisted.

8. Install the boot on the piston, slide the piston into the bore and gently tap the boot into the counterbore of the caliper housing using a suitable driver.

9. Install bleeder screw.

CAUTION

After the caliper has been installed and the system bled, before moving the vehicle, pump the brake pedal several times until the pedal is firm. Do not move the vehicle until a firm pedal is obtained. Check the fluid level in the master cylinder after pumping the brakes.

Wheel Cylinder Service

The drum brake assembly is a duo-servo design. Force which is applied by the wheel cylinder to the primary shoe is multiplied by the primary shoe friction to provide a large applied force to the secondary shoe. The torque from the brake shoes is transferred to the anchor pin and through the backing plate, the axle flange. Brake adjustments are automatic and are made during reverse brake applications.

Wheel cylinders may need reconditioning or replacement whenever the brake shoes are replaced or when required to correct a leak condition. In some cases, the wheel cylinders can be disassembled without removing them from the backing plate. On others, the cylinder must be removed before being disassembled.

Leaks which coat the boot and the cylinder with fluid, or result in a dropped reservoir fluid level, or dampen and stain the brake linings are dangerous. Such leaks can cause the brakes to grab or fail and should be immediately corrected. A leakage, not immediately apparent, can be detected by pulling back the cylinder boot. A small amount of fluid seepage dampening the interior of the boot is normal. However, a dripping boot is not. Unless other conditions causing a brake to pull, grab or drag become obvious, the wheel cylinder is suspect and should and should be included in general reconditioning.

Cylinder binding may be caused by rust, deposits, grime, or swollen cups due to fluid contamination, or by a cup wedged into an excessive piston clearance.

Hydraulic system parts should not be allowed to come into contact with oil or grease, neither should those be handled with greasy hands. Even a trace of any petroleum based product

Caliper components—typical

Wheel cylinder components—typical

is sufficient to cause damage to the rubber parts.

Disassembly and Assembly

1. Remove the brake bleeder screw.
2. Remove the dust boots, allow any brake fluid to drain out.
3. Remove the pistons, seals and inner spring.
4. Inspect the bore for scoring and corrosion. The inside of the bore may be cleaned with fine crocus cloth. If bore is scored, replace cylinder. Clean the cylinder with brake fluid.
5. Lubricate the seals with brake fluid and install. Cup lips should always face inward. Install the spring assembly and seals.
6. Carefully install the pistons and dust boots.
7. Install the bleeder screw.

Anti-Lock Braking Systems

Despite advances in brake design over the years, even the best systems in use

can still lock up during certain road conditions, such as wet road surfaces. When the brakes lock up, the driver can lose control of the vehicle, because a locked wheel cannot absorb any cornering or lateral forces, and steering is lost. It is impossible to brake to a maximum and at the same time steer the vehicle when the front wheels are locked. If the back wheels are locked the vehicle will become unstable and start to slide.

While many different ways have been tried over the years to solve this problem, mechanical sensors could not provide sufficient information about wheel rotation speed and mechanical control units could not operate the brakes fast enough to prevent brake lockup.

The growth of the electronics industry has allowed small computers (microprocessors) to be reduced in both size and cost. Coupled with fast reacting electronic sensors, anti-lock braking has become more reliable with widespread application.

REAR WHEEL ANTI-LOCK BRAKE SYSTEM

General Motors Corporation's system is called Rear Wheel Antilock System (RWAL) and its application is on selected 2WD models. It is designed to reduce the occurrence of the rear wheel lockup during a severe brake application.

The system functions by regulating the rear hydraulic brake line pressure. The pressure regulation is accomplished by a control valve which is located under the master cylinder. The control valve is made up of 2 valves, a dump valve which releases pressure

into an accumulator, and an isolation valve which maintains rear brake pressure. The valve is controlled by a microcomputer which is part of the Electronic Control Unit (ECU). The ECU is mounted next to the master cylinder. In a severe brake application as pressure is applied to the brake pedal, the ECU is designed to permit the valve to do one of three functions or a combination of all three. The ECU will allow the valve to either maintain the same amount of hydraulic pressure, release hydraulic pressure through the dump valve into the accumulator, or increase the pressure by pulsing the isolation valve.

The ECU operates by receiving signals from the speed sensor which is located in the transmission and the brake lamp switch. The speed sensor sends its signal to the digital ratio adapter which is part of the instrument cluster. If the axle ratio or tire size is changed, it will be necessary to recalibrate the digital ratio adapter.

The RWAL system is connected to the existing brake warning lamp located on the dash. An indication of the RWAL operation is a bulb check performed each time the ignition is turned ON. The warning lamp will remain on for about two seconds. A RWAL system malfunction is indicated by a brake warning lamp.

To aid in diagnosing problems, trouble codes are produced by the system. Trouble codes are available at the ALDL (Assembly Line Diagnostic Link) the twelve terminal connector wired to the Electronic Control Module and located under the instrument panel in the passenger compartment. These codes are read by jumping terminal A (which is ground) of the ALDL

to terminal H of the ALDL and observing the flashing of the brake warning light. The terminals must be jumped for about 20 seconds before the code will begin to flash. In counting code pulses, count the number of short flashes starting from the long flash. Include the long flash as a count.

NOTE: Sometimes the first count sequence will be short. However, subsequent counts will be accurate. If there is more than one failure, only the first recognized failure code will be retained and flashed.

To clear trouble codes, with the igni-

tion OFF, remove the brake fuse, wait five seconds, and then reinstall fuse.

Circuit Maintenance and Repair

All electrical connections must be kept clean and tight. Make sure that connectors are properly seated and all of the sealing rings on weather-proof

Trouble codes are available at the ALDL (Assembly Line Diagnostic Link), the twelve terminal connector wired to the Electronic Control Module and located under the instrument panel in the passenger compartment. These codes are ready by jumping terminal A (which is ground) of the ALDL to terminal H of the ALDL and observing the flashing of the brake warning light.

connections are in place. With the low current and voltage levels found in some circuits, it is important that all connections be the best possible. Special tools are required for servicing GM's Weather-Pack connectors. This special tool is required to remove the pin and sleeve terminals. If removal is attempted with an ordinary pick, there is a good chance that the terminal will be bent or deformed. These terminals cannot be straightened once they are bent.

Use care when probing the connections or replacing terminals in them. It is possible to short between opposite terminals. If this happens to the wrong terminal part, it is possible to damage certain components. Always use jumper wires between connectors for circuit checking. Never probe through Weather-Pack seals.

When diagnosing for possible open circuits, it is often difficult to locate them by sight because oxidation or terminal misalignment are hidden by the connectors. Merely wiggling a connector on a sensor or in the wiring harness may correct the open circuit condition. This should always be considered when an open circuit is indicated while troubleshooting. Intermittent problems may also be caused by oxidized or loose connections.

Removal and Installation

RWAL ELECTRONIC CONTROL UNIT

The RWAL Electronic Control Unit (ECU) is not serviceable. It should be replaced when diagnosis shows it to be malfunctioning.

NOTE: Do not touch the electrical connections and pins or allow them to come into contact with brake fluid as this will damage the RWAL ECU.

1. Disconnect the electrical connectors.
2. Remove the RWAL ECU by prying the tab at the rear of the ECU and pulling it forward toward the front of the vehicle.
3. To install, simply slide the RWAL ECU into its bracket on the master cylinder until the tab locks into the hole.
4. Install the electrical connectors. If brake fluid has gotten on the connectors, clean then with water followed by isopropyl alcohol.

ISOLATION/DUMP VALVE

The Isolation/Dump valve is not serviceable. It should be replaced when diagnosis shows it to be malfunctioning.

NOTE: Do not touch the electrical connections and pins or allow them to come into contact with brake fluid as this will damage the RWAL ECU.

1. Disconnect the brake line fittings and remove the bolts holding the valve to the bracket.
2. Disconnect the electrical connector from the RWAL ECU. Do not allow the valve to hang by the pigtail.
3. Remove the valve from the vehicle.
4. When installing replacement valve, torque bolts to 21 ft. lbs, brake line fittings to 18 ft. lbs.
5. Install the electrical connectors.

RWAL ECU and Isolation/Dump Valve

Digital ratio adapter controller mounting

DIAGNOSIS OF THE VEHICLE SPEED SENSOR AND DIGITAL RATIO ADAPTER CONTROLLER

Problem	Possible Cause	Correction
Speedometer and odometer are inaccurate	Incorrect digital ratio adapter.	Check for the correct digital ratio adapter.
Speedometer and odometer do not operate properly	1. Inoperative digital ratio adapter. 2. Poor ground path from the digital ratio adapter. 3. No signal from the vehicle speed sensor. 4. Inoperative digital ratio adapter (speedometer output). 5. Inoperative digital ratio adapter (cruise output). 6. Inoperative instrument cluster.	1. Disconnect the digital ratio adapter, and place the ignition in run. Check for voltage between the pink/black wire in the harness and a good chassis ground. If the voltage is less than the battery voltage, check for an open or short in the pink/black wire. 2. Check for voltage between the pink/black wire in the harness and the black/white wire. If the voltage is less than battery voltage, check for an open or short in the black/white wire. 3. Raise and support the vehicle, start the engine, and place the transmission in drive. Check for AC voltage that changes with the engine rpm between the purple/white wire, and the light green/black wire at the digital ratio adapter. If there is not AC voltage at these wires, check for opens in the purple/white wire and the light green wire. If there are not shorts or opens, replace the vehicle speed sensor. 4. Raise and support the vehicle, start the engine, and place the transmission in drive. Check for AC voltage that changes with the engine rpm between the light blue/black and the black/white wires at the digital ratio adapter connector (connector attached) if AC voltage varies with RPM, replace the digital ratio adapter. 5. Raise and support the vehicle, start the engine, and place the transmission in drive. Check for AC voltage that changes with the engine rpm between the yellow and the black/white wires at the digital ratio adapter connector (connector attached) if AC voltage varies with rpm, replace the digital ratio adapter. 6. Refer to DIAGNOSIS OF THE ELECTRONIC INSTRUMENT CLUSTER.

If brake fluid has gotten on the connectors, clean them with water followed by isopropyl alcohol.

6. Bleed brake system.

SPEED SENSOR

The vehicle speed sensor is a permanent magnet signal generator located on the transmission output shaft housing. The vehicle speed sensor sends an analog signal proportional to the propeller shaft speed. This signal

goes to the Digital Ratio Adapter Controller (DRAC) which is used to change the speed sensor signal to a digital signal for the electronic instrument cluster.

The speed sensor is not serviceable. It should be replaced when necessary. The sensor is located in the left rear of the transmission on 2WD models and on the transfer case of 4WD models.

The resistance of the speed sensor should be 900-2000 ohms.

1. Remove the electrical connector.
2. Most applications will use a bolt retainer which is removed. Pull the speed sensor out of transmission housing. Have container ready to catch transmission fluid.

3. Always use new O-ring seal when installing speed sensor. Coat the seal with a thin film of transmission fluid.

4. Install retainer bolt if used and connect electrical harness.

NOTE: The speedometer must be recalibrated when rear axle ratio or tire size is changed.

FOUR WHEEL ANTI-LOCK BRAKE SYSTEM

In 1990, selected G.M. models with All Wheel Drive (AWD) could be equipped with a Four Wheel Antilock System (4WAL). It too is designed to reduce wheel lockup during severe braking. Like the Rear Wheel Antilock system, it works by regulating hydraulic brake line pressure. An Electro-Hydraulic Control Unit valve (EHCUC), located under the master cylinder, is made up of two types of valves. Isolation valves maintain pressure to each front wheel separately and to the rear wheels combined. Dump valves dump pressure to each front wheel separately and to the rear wheels combined. The valves are controlled by a microcomputer which is part of the EHCUC valve. Under severe braking, the EHCUC valve will al-

low the valves to either maintain the same hydraulic pressure, release hydraulic pressure through the dump valves into the accumulator, or increase pressure.

The EHCUC valve operates by receiving signals from the speed sensors, located at each wheel and the brake lamp switch. The speed sensors are connected directly to the EHCUC valve through the 8 pin connector.

The 4WAL system is connected to the ANTILOCK warning lamp in the instrument panel. An indication of 4WAL operation and a bulb check is performed each time the ignition is turned ON. The warning lamp will remain on for about 2 seconds. A 4WAL system malfunction is indicated by the ANTILOCK warning light.

To aid in diagnosing problems, trouble codes are produced by the system. Trouble codes are available at the Assembly Line Diagnostic Link (ALDL) the twelve terminal connector wired to the Electronic Control Module and located under the instrument panel in

the passenger compartment. These codes are read by jumping terminal A of the ALDL to terminal H of the ALDL and observing the flashing of the ANTILOCK. The terminals must be jumped for a few seconds before the code will begin to flash. The ANTILOCK light will flash in a manner similar to the SERVICE ENGINE SOON light for the fuel and emissions system.

In counting code pulses, count the number of short flashes starting from the long flash. Include the long flash as a count.

NOTE: Sometimes the first count sequence will be short. However, subsequent counts will be accurate. If there is more than one failure, only the first recognized failure code will be retained and flashed.

To clear trouble codes, turn the ignition switch to RUN. Use a jumper wire to ground the ALDL terminal H to A for two seconds. Remove the jumper wire for two seconds. Repeat the grounding and ungrounding 2 more times. Check that the memory is cleared by making a diagnostic request. Turn ignition OFF.

Removal and Installation

ELECTRO-HYDRAULIC CONTROL UNIT (EHCU) VALVE

The EHCU valve is not serviceable. It should be replaced when diagnosis shows it to be malfunctioning.

1. Mark relationship between the intermediate steering shaft upper universal joint yoke to steering shaft and the lower yoke to steering gear wormshaft. Remove the upper and lower universal yoke pinch bolt.

2. Remove the steering gear frame bolts. Lower the steering gear. It is not necessary to disconnect the pitman arm from the steering gear pitman shaft.

3. Remove the intermediate steering shaft and universal joint assembly.

4. Remove the brake lines from the

Remove steering intermediate shaft to remove EHCU

EHCU valve mounting

EHCU valve brake line connections

Front wheel speed sensor — 2 WD vehicles

bottom of the combination valve. Remove the electrical connector.

5. Remove the master cylinder and combination valve assembly.

6. Remove the brake lines from the EHCU valve. Remove the electrical connectors from the EHCU valve.

7. Remove mounting bolt and nuts and remove EHCU from vehicle. Remove EHCU from its mounting bracket.

8. Install the EHCU valve to its mounting bracket. Tighten the 6 mounting bolts to only 60 inch lbs. Overtightening these bolts could result in excessive noise transfer from the EHCU valve.

9. Install the EHCU valve and bracket assembly into the vehicle and install the fasteners. Torque the bolt to 33 ft. lbs., the nuts to 20 ft. lbs.

10. Install the electrical connectors and the brake lines to the EHCU valve.

11. Install the master cylinder and combination valve assembly. Connect the electrical connector and the brake lines to the combination valve.

12. Install the steering intermediate shaft. Start by placing the lower yoke onto the steering gear wormshaft.

Align the match marks made at removal. Install the pinch bolt which must pass through the shaft undercut. Torque to 30 ft. lbs.

13. Raise the steering gear into position while guiding the upper yoke onto the steering shaft. Align the match marks made at removal. Tighten the steering gear to frame bolts to 55 ft. lbs. Install the pinch bolt which must pass through the shaft undercut. Torque to 30 ft. lbs.

14. Bleed the brake system including the EHCU valve.

NOTE: The EHCU valve should be bled after replacement only. It should not be necessary to bleed the valve during normal brake system bleeding. The valve should be bled after the wheel cylinders and calipers have been bled. Use the 2 bleed screws on the EHCU valve for bleeding. There are also 2 bleeders on the front of the unit that look like normal brake bleeders. These are not the correct bleeders for bleeding the EHCU valve and they should not be turned. A special tool is used to depress the high pressure accumulator bleed stem of the EHCU valve. This is similar to tools used to hold the stem of proportioning valves during bleeding.

15. Bleed the wheel cylinders and calipers as usual (right rear, left rear, right front, left front).

16. Install the special hold-down tool on the left high pressure accumulator bleed stem of the EHCU valve.

17. Slowly depress brake pedal one time and hold. Loosen the left bleeder screw $\frac{1}{4}$ – $\frac{1}{2}$ turn to purge air from the EHCU valve. Tighten the bleeder screw and slowly release the pedal.

18. Wait 15 seconds then repeat this sequence including the 15 second wait until all air is purged from the EHCU valve.

EHCU valve bleeders

19. Repeat these steps on the right side of the EHCU valve.

20. Remove valve depressor tool.

FRONT WHEEL SPEED SENSOR

2 WD Vehicles

1. Raise and safely support vehicle. Remove wheel and tire assembly.

2. Remove brake caliper.

3. Remove hub and bearing assembly.

4. Remove rotor assembly.

5. Disconnect the sensor wire connector and unclip from upper control arm.

6. Remove bolts holding speed sensor/splash shield assembly and remove unit from vehicle.

7. Install speed sensor/splash shield assembly and torque bolts to 11 ft. lbs.

8. Clip wire to upper control arm and reconnect electrical connection.

9. Apply recommended lubricant to the spindle and inside of hub. Install hub and outer wheel bearing and washer with a generous amount of lubricant. Tighten nut to 12 ft. lbs. while turning the hub forward to seat the bearing. Back off the nut to the just loose position. Hand tighten nut, then back off until the hole in the spindle lines up with a slot on the nut. The nut should not be backed off more than 1/2 a flat. Install new cotter pin.

10. Install brake rotor.

11. Install caliper. Bushings should be lubricated with silicone grease. Make sure the brake line is not twisted.

12. Install wheel and tire assembly. Lower vehicle.

4WD Vehicles

1. Raise and safely support vehicle. Remove wheel and tire assembly.

2. Remove brake caliper.

3. Remove brake rotor.

4. Remove hub and bearing assembly. On all-wheel drive models, remove the drive axle nut and washer. Use a puller to ease the hub from the drive axle.

5. Disconnect the sensor wire connector and unclip from upper control arm.

6. Remove bolts holding speed sensor/splash shield assembly and remove unit from vehicle.

7. Install speed sensor/splash shield assembly to the steering knuckle and torque the bolts to 11 ft. lbs.

8. Clip wire to upper control arm and reconnect electrical connection.

9. Install hub and bearing assembly, align threaded holes and tighten bolts to 66 ft. lbs.

10. Install outer axle washer and nut. Torque to 175 ft. lb.

11. Install brake rotor and caliper.

12. Install wheel and tire. Lower vehicle.

Rear wheel speed sensor

REAR WHEEL SPEED SENSOR

4WD Vehicles

1. Raise and safely support vehicle. Remove wheel and tire assembly.

2. Remove brake drum.

3. Remove the primary brake shoe.

4. Disconnect the sensor electric wire connector and wire from its axle clips.

5. Remove the retainer bolts and take out speed sensor by pulling the wire through the hole in the backing plate.

6. Install the speed sensor and bolts. Torque to 26 ft. lbs.

7. Install sensor wire to axle clips and hook up connector.

8. Install primary brake shoe, brake drum and wheel and tire assembly. Lower vehicle.

FORD MOTOR COMPANY

Master Cylinder Service

Ford Motor Company uses a dual master cylinder which contains a double hydraulic cylinder with 2 fluid reservoirs and primary and secondary hydraulic pistons. The rear wheel brakes are connected to the secondary outlet port and are actuated by the secondary piston assembly. The front wheel brakes are connected to the primary outlet port (nearest the dash panel) and are actuated by the primary piston assembly. Both primary and secondary pistons function together. On most models, the master cylinder

is assisted by a vacuum booster. Both single and double diaphragm Bendix models are used. Hydraulic rear drum brakes with automatic adjusters and self-adjusting front disc brakes are standard on all models.

Two types of master cylinders were used by Ford Motor Company; 1) a cast iron master cylinder with built-in reservoir and separate proportioning valve and, 2) a master cylinder with a pressed on plastic see-through reservoir with the proportioning valve built into or integral with the master cylinder. In the event of a front brake system malfunction the proportioning valve with a bypass feature allows full hydraulic pressure to the rear brake system.

A Fluid Level Indicator (FLI) is built into the reservoir. It is serviced as part of the reservoir assembly. This master cylinder is found from 1987.

During normal operation, the fluid level in the master cylinder will rise during brake operation and fall during release. It is also expected that the fluid level will decrease with brake pad wear. In addition, a trace of brake fluid on the booster shell below the master cylinder mounting flange will often be found as a result of the normal lubricating action of the master cylinder bore and seal. All of these conditions are considered normal and are not indications the master cylinder needs service.

Disassembly and Assembly

CAST IRON MASTER CYLINDER

1. Clean outside of master cylinder, remove cover and diaphragm. Drain and discard remaining brake fluid.

2. Depress the primary piston and remove snapping at rear of the master cylinder bore.

3. Remove the primary piston and inspect for damage.

4. Remove the secondary piston assembly by directing a little compressed air into the outlet at the blind end of the bore while plugging the other outlet port.

5. Inspect the pistons, seals and cylinder bore for etching, pitting, scoring or other damage. If the bore is damaged, discard and replace with a new master cylinder. Do not attempt to hone the bore. If the bore is not damaged, use the proper repair kit to rebuild.

6. Clean the master cylinder body with isopropyl alcohol.

7. Dip the repair kit piston assemblies in clean heavy duty brake fluid to lubricate the seals. Carefully insert the complete secondary piston assembly into the master cylinder bore, followed by the primary piston assembly.

8. Depress the primary piston and

install snapping. On manual brake vehicle, install the push rod retainer onto the push rod and install into primary piston. Make sure retainer is properly seated and holding the push-rod securely.

9. Install cover and gasket and secure with retainer.

PLASTIC RESERVOIR MASTER CYLINDER

1. Clean the outside of the master cylinder and remove the cap and gasket. Drain and discard remaining brake fluid.

2. Remove the proportioning valve from the master cylinder.

3. Remove the stop-bolt from the bottom of the master cylinder assembly.

4. Depress the secondary piston, remove the snapping from the bore and remove the secondary piston assembly.

5. Remove the primary piston assembly by directing a little compressed air into the outlet at the blind end of the bore while plugging the other outlet port.

Ford master cylinder with see-through reservoir and integral proportioning valve

Plastic reservoir with fluid level indicator

6. Inspect the pistons, seals and cylinder bore for etching, pitting, scoring or other damage. If bore is damaged, discard and replace with a new master cylinder. Do not attempt to hone the bore. If the bore is not damaged, use the proper repair kit to rebuild.

7. If plastic reservoir is to be removed, carefully pry the reservoir from the master cylinder body. The plastic reservoir is a push-fit with rubber grommets making the seal. Whenever the plastic reservoir is replaced, the grommets must also be replaced.

8. Dip the repair kit piston assemblies in clean heavy duty brake fluid to lubricate the seals. Carefully insert the complete primary piston assembly into the master cylinder bore, followed by the secondary piston assembly.

8. Depress the secondary piston and install snapping. Install the stop bolt in the bottom of the master cylinder bore.

9. Install the proportioning valve assembly in the master cylinder.

10. If the reservoir was removed, lubricate new retainer grommets with brake fluid and insert the grommets into the master cylinder body. Press the plastic reservoir into the grommets. The reservoir should snap into place indicating that it is secure. Make sure the fluid level indicator socket is facing the correct direction for the vehicle on which it is to be installed.

11. Install plastic cap on the master cylinder.

Brake Booster Service

Three types of brake boosters are used, a single diaphragm, a tandem diaphragm and a hydraulic booster (Hydro-Boost).

Under normal operating conditions, with brakes released, a vacuum suspended booster operates with vacuum on both sides of its diaphragm (or both diaphragms in a tandem diaphragm unit). When the brakes are applied, air at atmospheric pressure is admitted to one side of the diaphragm (or both diaphragms in a tandem diaphragm unit) to provide the power assist.

The hydraulic brake booster (Hydro-Boost) uses the power steering pump to power the system and a pneumatic accumulator as a reserve system. In this system no special fluids are used. However, care must be taken to use the correct fluids. The master cylinder and brake system operate on standard brake fluid. The hydraulic pump uses power steering fluid.

VACUUM DIAPHRAGM BRAKE BOOSTER

Both the Bendix single diaphragm and

Bendix tandem diaphragm booster are not repairable and the booster must be replaced as a unit. The booster check valve is the only component which can be serviced on the booster assembly.

The Bendix Hydro-Boost uses the hydraulic pressure supplied by the power steering pump to provide a power assist to brake application. It has identifying information stamped into the housing near the inlet.

The Hydro-Boost power brake booster is not to be disassembled and is to be serviced as a unit.

Brake Booster Vacuum Pump

On gasoline engine vehicles, engine vacuum is used to power the vacuum booster brake. On diesel engines, there is not enough vacuum available for vacuum booster brake operation.

On diesel engine vehicles, vacuum is supplied from a pump usually located on the top right side of the engine. It is usually driven by a single belt off the alternator.

Diesel engine equipped vehicles will also usually have a low-vacuum indicator switch which activates the BRAKE warning lamp when vacuum gets below a certain level. The switch senses vacuum through a fitting in the vacuum manifold (sometimes called a vacuum tree). Note that the BRAKE light will glow until vacuum builds up to normal level.

The low-vacuum switch for E Series is located to the left side fender panel. On F 250-F 350 Series the switch is located on the right side of the engine compartment adjacent to the vacuum pump.

The vacuum pump is not to be disassembled. It is only serviced as a unit. The pulley is serviced as a separate item.

Caliper Service

Ford Motor Company uses several types of brake calipers, a Heavy Duty (HD) Pin Rail caliper, a Light Duty (LD) sliding brake caliper and a Light Duty (LD) Pin Rail caliper.

The HD caliper has 2 pistons on the same side of the rotor. Pin Rail type calipers slide on 2 pins that also attach the caliper to the spindle (or anchor plate on some F-Super Duty rear disc brakes). The caliper is a one-piece casting with the inboard side containing the piston bore(s). A square cut rubber seal is located in a groove in the piston bore which provides the hydraulic seal between the piston and the cylinder wall.

As the brake pedal is pressed, hy-

Vacuum pump installation—typical

Vacuum pump layout—Econoline shown—typical

BRAKE BOOSTER VACUUM PUMP TESTING—DIESEL ENGINES

TEST	PROCEDURE
Test 1	Isolating Problem A. Disconnect Low Vacuum Switch. Run engine at idle, apply brakes. • If brake warning light comes on, the problem is in the hydraulic brake system. • If brake warning light does not come on, the problem is in the vacuum pump (perform Test 2).
Test 2	Vacuum Pump Output Check A. Hook up vacuum gauge to hose at brake booster. At normal idle, vacuum should reach 21 inches Hg within 30 seconds (approximately 16 inches Hg at high altitudes—5,000 ft.). • If vacuum is okay, reconnect booster base and "TEE" vacuum gauge near pump inlet. Check vacuum at idle. There should be no more than 3 inches Hg vacuum drop. If drop is greater, look for vacuum leaks at hoses or vacuum accessories. • If vacuum is okay, repeat test with brake pedal held down. If vacuum drops, replace brake booster. If vacuum is within specs, check brake hydraulic system. • If vacuum is not okay, check gauge and connector for leaks. Make sure pulley is not slipping on shaft, and belt tension is okay. Make sure engine idle speed is correct. If vacuum output is still low, replace vacuum pump.

NOTE: When making tests, block all wheels, place transmission in Park or Neutral before starting engine.

draulic pressure is applied against the piston(s). This pressure pushes the inboard brake lining against the inboard braking surface of the rotor. As the force increases against the rotor, the caliper assembly moves inboard and provides a clamping action on the rotor.

When brake pressure is released, the piston seal returns to its normal position, pulling the piston back into the caliper bore. This creates a running clearance between the inner brake lining and rotor.

NOTE: Some Ford trucks were available with four wheel disc brakes.

Front caliper—Ford HD rail slider

Disc caliper—Front and rear, F-Super Duty

Disc caliper—Ford LD sliding caliper

Disassembly and Assembly

1. Remove pads from caliper. Different types of anti-rattle springs have been used. Note their positions for re-assembly. Drain all fluid from the caliper.

2. Pad interior of caliper with clean shop towels or soft wood block and slowly and carefully use just enough compressed air to ease the piston out of the bore.

CAUTION

Do not place fingers in front of piston to try to catch piston or protect it when applying compressed air. This could result in serious injury. Use just enough air to ease the piston out. If piston is blown out, even with padding, it may be damaged. If the piston is jammed or cocked and will not come out readily, release the air pressure and tap sharply on the end of the piston with a soft (brass) hammer or plastic mallet to straighten the piston. Do not use a sharp tool to pry the piston out of the bore.

3. Remove and discard seal boot, being careful not to scratch bore.

4. Remove and discard square cut seal from caliper bore groove.

5. Remove bleeder valve.

6. Clean all parts with denatured alcohol, blow dry with compressed air. Inspect all parts for scoring, corrosion

or damage. If the caliper assembly is leaking, replace the piston assemblies. If the cylinder bores are scored, corroded or excessively worn, replace the caliper. Do not hone the cylinder bores. Piston assemblies are not available for oversize bores.

NOTE: Some versions of Ford calipers came with phenolic (plastic) pistons. These do not have to be replaced for small cosmetic surface irregularities or small chips between the piston boot grooves and the shoe face.

7. Lubricate the new piston seals, caliper bore and piston with clean brake fluid and install the seal in the caliper bore groove. Make sure seal is not twisted.

8. Lubricate the retaining lips of the dust boots with clean brake fluid and install them in the boot retaining grooves in the cylinder bores. Insert the pistons into the dust boots and start them into the cylinder by hand until they are beyond the piston seals. Be careful not to damage or dislodge the piston seal. Place a wood block over one piston and press the piston into the cylinder being careful not to cock the piston in the cylinder. Install the second (of dual piston calipers) in the same manner. Make sure boots are correctly seated.

9. Install bleeder screw.

10. Install shoe and lining assemblies, using care to get the anti-rattle clips correctly positioned. New copper washers should be used when the caliper is installed and the brake hose reconnected. The machined surfaces of the caliper mount should be wire brushed smooth and clean so the caliper will be able to move freely.

NOTE: After the caliper has been installed and the system

bled, before moving the vehicle, pump the brake pedal several times until the pedal is firm. Do not move the vehicle until a firm pedal is obtained. Check the fluid level in the master cylinder after pumping the brakes.

Wheel Cylinder Service

The rear brakes are drum type with internal expanding shoes. The rear brakes are of the single anchor type, mounted to the same anchor and actuated by one wheel cylinder. The wheel cylinder has 2 pistons. Brake adjustments are automatic and are made during reverse brake applications.

Wheel cylinders may need reconditioning or replacement whenever the brake shoes are replaced or when required to correct a leak condition. Leaks which coat the boot and the cylinder with fluid, or result in a dropped reservoir fluid level, or dampen and stain the brake linings are dangerous. Such leaks can cause the brakes to grab or fail and should be immediately corrected. A leakage, not immediately apparent, can be detected by pulling back the cylinder boot. A small amount of fluid seepage dampening the interior of the boot is normal. However, a dripping boot is not. Unless other conditions causing a brake to pull, grab or drag become obvious, the wheel cylinder is suspect and should and should be included in general reconditioning.

Cylinder binding may be caused by rust, deposits, grime, or swollen cups due to fluid contamination, or by a cup wedged into an excessive piston clearance.

Hydraulic system parts should not be allowed to come into contact with oil or grease, neither should those be handled with greasy hands. Even a trace of any petroleum based product is sufficient to cause damage to the rubber parts.

Disassembly and Assembly

1. Remove the brake bleeder screw.
2. Remove the dust boots, allow any brake fluid to drain out.
3. Remove the pistons, seals and inner spring.
4. Inspect the bore for scoring and corrosion. The inside of the bore may be cleaned with fine crocus cloth. If bore is scored, replace cylinder. Clean the cylinder with brake fluid.
5. Lubricate the seals with brake fluid and install. Cup lips should always face inward. Install the spring assembly and seals.

6. Carefully install the pistons and dust boots.

7. Install the bleeder screw.

Anti-Lock Braking Systems

Despite advances in brake design over the years, even the best systems in use can still lock up during certain road conditions, such as wet road surfaces. When the brakes lock up, the driver can lose control of the vehicle, because a locked wheel cannot absorb any cornering or lateral forces, and steering is lost. It is impossible to brake to a maximum and at the same time steer the vehicle when the front wheels are locked. If the back wheels are locked the vehicle will become unstable and start to slide.

While many different ways have been tried over the years to solve this problem, mechanical sensors could not provide sufficient information about wheel rotation speed and mechanical control units could not operate the brakes fast enough to prevent brake lockup.

The growth of the electronics industry has allowed small computers (microprocessors) to be reduced in both size and cost. Coupled with fast reacting electronic sensors, anti-lock braking has become more reliable with widespread application.

REAR WHEEL ANTI-LOCK BRAKE SYSTEM

Ford Motor Company's Rear Antilock Brake System (RABS) continually monitors rear wheel speed with a sensor mounted on the rear axle. When the teeth on an exciter ring, mounted inside the rear axle on the differential gear case, pass the sensor pole piece, an AC voltage is induced in the sensor circuit with a frequency proportional to the average rear wheel speed. In the event of an impending lockup condition during braking, the RABS modulates hydraulic pressure to the rear brakes. This inhibits rear wheel lockup.

When the brake pedal is applied, the RABS module senses the drop in rear wheel speed. If the rate of deceleration is too great, indicating the wheel lockup is going to occur, the RABS module activates the electro-hydraulic valve causing isolation valve to close. With the isolation valve closed, the rear wheel cylinders are isolated from the master cylinder and the rear brake pressure cannot increase. If the rate of deceleration is still too great, the RABS module will energize the dump solenoid with a series of rapid pulses to

bleed off rear wheel cylinder fluid into an accumulator built into the RABS valve. This will reduce the rear wheel cylinder pressure and allow the rear wheels to spin back up to vehicle speed. Continuing under RABS module control, the dump and isolation solenoids will be pulsed in a manner that will keep the rear wheels rotating while still maintaining high levels of deceleration during braking.

At the end of the stop, when the operator releases the brake pedal, the isolation valve de-energizes and any fluid in the accumulator is returned to the master cylinder. Normal brake operation is resumed.

System Self Test

The RABS module performs system tests and self-tests during startup and normal operation. The valve, sensor, and fluid level circuits are monitored for proper operation. If a fault is found the RABS will be deactivated and the REAR ANTILOCK light will be illuminated. Most faults will cause the light to stay illuminated until the ignition is turned OFF. While the light is illuminated a diagnostic flashout code may be obtained. However, there are certain faults (those associated with the fluid level switch or loss of power to the module) that will cause the system to be deactivated and the REAR ANTILOCK light to be illuminated but will not provide a diagnostic flashout code will be available.

Warning Lights

The RABS uses both the BRAKE and REAR ANTILOCK instrument panel warning lights to alert the driver to a system malfunction. Both lights must be working properly to assist in problem diagnosis. The red BRAKE warning light is used to indicate a low fluid level condition, parking brake applied condition or, for vehicles equipped with diesel engines, a low vacuum condition. To check this light, turn the key to START. The light should glow in this position. If it fails to glow, service of the electrical system is required.

NOTE: If the red light continues to glow after the key is in the RUN position, repair the brake system as required. If the brake system checks out OK, troubleshooting will be required to diagnose the RABS problem.

The yellow REAR ANTILOCK warning light is used to indicate an RABS malfunction and a deactivation of the RABS. To check this light, turn the key to ON or START. The light should perform a self-check, glowing for about 2 seconds. If the light fails to

glow or continues to glow after two seconds, troubleshooting of the warning lights is required.

A diode/resistor is located on the main trunk of the instrument panel wiring harness where the RABS module connector pigtail intersects the main trunk. The diode/resistor isolates the RABS module from the parking brake switch and the low vacuum switch (diesel engines). If the diode/resistor did not prevent voltage from reaching the RABS module, the yellow REAR ANTILOCK lamp would turn on and the system would be shut down whenever the parking brake was applied or the low vacuum switch was closed.

Flashout Codes

Whenever the yellow REAR ANTILOCK light comes on during normal operation, a flashout code may be obtained to aid in problem diagnosis. If the vehicle is shut off before the code is read, the code will be lost. In some cases the code may reappear when the vehicle is restarted. In other cases, the vehicle may have to be driven to reproduce the problem and, if the problem was associated with an intermittent condition, it may be difficult to reproduce. Therefore, whenever possible, it is recommended that the code be read before the vehicle is shut off.

NOTE: Place blocks behind the rear wheels and in front of the front wheels to prevent the vehicle from moving while the flashout code is being taken. If the BRAKE light is also on, due to a grounding of the fluid level cir-

cuit (perhaps low brake fluid), no flashout code will be flashed and the REAR ANTILOCK light will remain on steadily. If there is more than one system fault only the first recognized flashout code may be obtained.

Obtaining the Flashout Code

A flashout code may be obtained only when the yellow REAR ANTILOCK light is ON. No code will be flashed if the system is operating properly.

Before obtaining the flashout code, drive the vehicle to a level area, and place the shift lever in P for automatic transmissions and neutral for manual transmissions.

Notice whether the red BRAKE light is on or not (for future reference) and then apply the parking brake. Keep the ignition ON so that the code will not be lost.

NOTE: Place blocks behind the rear wheels and in front of the front wheels to prevent the vehicle from moving while the flashout code is being taken.

To obtain the flashout code, locate the RABS diagnostic connector (with the black/orange wire) and attach a jumper wire to it. Momentarily ground it to the chassis. When the ground is made and then broken the REAR ANTILOCK light should begin to flash.

NOTE: If the red BRAKE light was on (as noticed before the parking brake was applied) the problem may be with the low fluid level circuit and, in this case, no

flashout code will be flashed and the light will remain on steadily.

The code consists of a number of short flashes and ends with a long flash. Count the short flashes and include the following long flash in the count to obtain the proper code number. For example, three short flashes followed by one long flash indicates Flashout Code Four. The code will continue to repeat itself until the key is turned off. It is recommended that the code be verified by reading it several times. In addition, the first code flashed may be too short because it may have been started in the middle. It should be ignored.

COMPONENT LOCATION

F SERIES AND BRONCO

The RABS consists of the following components:

1. RABS module located in the cab to the right of the brake pedal under the upper dash panel.
2. RABS valve (dual solenoid electro-hydraulic) is located on the left frame rail just behind the number one crossmember.
3. RABS speed sensor located on the rear axle housing and the exciter ring is located inside on the gear carrier.
4. Yellow REAR ANTILOCK warning light is in the instrument cluster.
5. RABS diagnostic connector is located in the cab and clipped on the main instrument panel wiring harness about six inches from the firewall near the parking brake pedal.
6. Diode/resistor element is located

FORD REAR WHEEL ANTILOCK BRAKE SYSTEM DIAGNOSTIC CODES

Codes Are Yellow REAR ANTILOCK Light Flashing—Count Flashes

CODE	SYSTEM PROBLEM
CODE 1	This code is not used and should not occur
CODE 2	Open isolate circuit
CODE 3	Open dump circuit
CODE 4	Check RABS valve
CODE 5	Check RABS valve/4 × 4 indicator switch (4WD)
CODE 6	Check sensor for loose connections, chips, bad exciter ring
CODE 7	No isolate valve self test
CODE 8	No dump valve self test
CODE 9	Check sensor wiring for high resistance
CODE 10	Check sensor wiring for low resistance (shorted)
CODE 11	Check stop lamp switch
CODE 12	Check for low fluid level, bad brake light wiring
CODE 13	RABS module failure—replace
CODE 14	RABS module failure—replace
CODE 15	RABS module failure—replace
CODE 16	This code is not used and should not occur

NOTE: CODES 1 and 16 are not used. When checking resistance in the antilock brake system, always disconnect the battery. Improper resistance readings will occur with the vehicle battery connected.

Component Location F-150—F-350, Bronco

RABS Component Location—F Series, Bronco shown—typical

18 BRAKES DOMESTIC

on the main trunk of the instrument panel wiring harness where the RABS module connector pigtail intersects the main harness trunk.

7. Speed Sensor test connector (with weatherproof cap) is located under the hood on the left wheel well.

E SERIES

The RABS consists of the following components:

1. RABS module is located in the cab on the driver's inside cowl panel just outboard of the parking brake mechanism.

2. RABS valve (dual solenoid electro-hydraulic) is located on the left inside frame rail just behind the engine mount crossmember.

3. RABS speed sensor located on the rear axle housing and the exciter ring is located inside on the gear carrier.

4. Yellow REAR ANTILOCK warning light is in the instrument cluster.

5. RABS diagnostic connector is located just off the module connector harness.

6. Diode/resistor element is located on the main trunk of the instrument panel wiring harness where the RABS module connector pigtail intersects the main harness trunk.

7. Speed sensor test connector (with weatherproof cap) is located under the hood between the battery and the right side engine compartment wall.

Removal and Installation

RABS MODULE

The RABS module, valve and sensor are serviced as assemblies and are not to be disassembled. The exciter ring is pressed on the differential case and, if removed for any reason, must be discarded.

F Series and Bronco

1. Disconnect the wire harness from the RABS module by depressing the plastic tab on the connector and pulling the connector off.

2. Remove the 2 screws that retain the module to the dash panel. Remove the module.

3. Place the module in position on the dash panel. Install and tighten the 2 retaining screws.

4. Connect the wiring harness to the module. Check the system for proper operation.

E Series

1. Remove the parking brake actuator assembly. Start by loosening the adjusting nut at the equalizer. On F-Super Duty series vehicles remove the clevis pin at the parking brake. Working from the engine compartment, re-

move the nuts attaching the parking brake control assembly to the dash panel.

2. Working under the instrument panel, remove the bolt attaching the control assembly to the lower flange of the instrument panel. Remove the parking brake cable from the control assembly clevis by compressing the conduit end fitting prongs (using 1/2 inch box wrench) holding the cable assembly to the control, remove the cable from the control. Remove the parking brake control.

3. Remove the 2 screws that hold the module to the cowl panel. Remove the module.

4. Disconnect the wiring harness from the RABS module by depressing the plastic tab on the connector and pulling the connector off.

5. Connect the wiring harness to the RABS module.

6. Place module in position on the cowl panel. Install and tighten the two retaining screws.

7. Install the parking brake actuator by connecting the forward ball end of the parking brake cable to the clevis of the control assembly, and insert the cable assembly into the control assembly. Install hair pin retainer.

8. Position the control assembly on the lower flange of the instrument panel and install the attaching bolt.

9. Working from the engine compartment, install and tighten the nuts that attach the parking brake control assembly to the dash panel. Torque to 15 ft. lbs.

10. Adjust the parking brake equalizer lever to its original position. On Super Duty series vehicles, install the parking brake clevis pin. Check cable tension and adjust if necessary.

11. Check the RABS and parking brake systems for proper operation.

RABS DUAL SOLENOID ELECTRO-HYDRAULIC VALVE

The dual solenoid electro-hydraulic valve is located on the left frame rail slightly behind the number one crossmember. The purpose of this valve as-

RABS Module - F Series, Bronco

RABS Module - E Series

sembly is to control hydraulic fluid pressure to the rear wheels based on RABS module signals.

F Series and Bronco

1. Disconnect the inlet and outlet brake lines from the RABS valve. Cap the lines.

2. Disconnect the wiring harness to the valve.

3. Remove the nuts retaining the valve to the frame rail and remove the valve.

4. Position the RABS valve on the frame rail. Install the three nuts and torque to 12-17 ft. lbs.

5. Connect the brake lines and tighten the larger fitting to 10-17 ft. lbs. and the smaller to 10-15 ft. lbs. Do not overtighten the fittings.

6. Bleed the brake system. It is not necessary to energize the valve electrically to bleed the rear brakes.

RABS VALVE

E Series

1. Disconnect the inlet and outlet brake lines from the RABS valve. Cap the lines.

2. Disconnect the wiring harness from the valve harness.

3. Remove the three screws holding the valve to the frame rail liner and remove the valve.

4. Position the RABS valve on the frame rail liner, install the three screws and torque to 19-24 ft. lbs.

5. Connect the brake valve wiring harness to the main harness connector.

6. Connect the brake lines and tighten the larger fitting to 10-17 ft. lbs. and the smaller to 10-15 ft. lbs. Do not overtighten the fittings.

7. Bleed the brake system. It is not necessary to energize the valve electrically to bleed the rear brakes.

RABS SENSOR

1. The RABS sensor is located on the rear axle housing. Remove the wiring connector.

2. Remove the sensor hold-down bolt and remove the sensor from the axle housing.

Speed sensor mounts to rear axle housing

Exciter ring for speed sensor is pressed on gear carrier

3. When installing, clean the axle mounting surface. Use care to keep dirt from entering the axle housing.

4. Inspect and clean the magnetized sensor pole piece to ensure that it is free from loose metal particles which could cause erratic system operation. Inspect the sensor O-ring for damage and replace if necessary.

5. Lightly lubricate the sensor O-ring with motor oil, align the sensor bolt hole and install. Do not apply force to the plastic sensor connector. The sensor flange should slide to the mounting surface. This will insure the air gap setting is between 0.005–0.045 in.

6. Inspect the blue sensor connector seal and replace it if missing or damaged. Push the connector on the sensor.

NOTE: The clearance between the sensor and the exciter ring should be no greater than 0.050 inches. To measure, remove the sensor from the axle carrier, and measure the height of the pole piece from the mounting face of the flange. Sensor pole should be 1.07–1.08 in. Measure the depth from axle housing mounting surface to the top of the exciter teeth. Subtract the two measurements to get the sensor gap.

EXCITER RING

The exciter ring is pressed onto the

differential case. To inspect it, remove the sensor from the axle housing.

View the exciter ring teeth through the sensor hole. Rotate the rear axle and check the exciter ring teeth for damage or breakage. Dented or broken teeth could cause the RABS system to function when not required. To replace the exciter ring, the differential case must be removed from the axle housing and the exciter ring pressed off the case. Upon removal, the exciter ring must be discarded. It is not to be reused.

FUSES

Three replaceable fuses are involved with RABS. The fuses are located in the fuse box. A 20 amp fuse protects the total RABS. A 15 amp fuse protects the red BRAKE and yellow REAR ANTILOCK warning lights. Another 15 amp fuse protects the four-way stop lamp cluster.

CHRYSLER CORPORATION

Master Cylinder Service

Chrysler Corporation uses a dual master cylinder which contains a double hydraulic cylinder with two fluid reservoirs and primary and secondary hydraulic pistons. On most models, the master cylinder is assisted by a vacuum booster. The unit is mounted on a 90 degree bracket on some models, directly to the dashboard on others. Hydraulic rear drum brakes with automatic adjusters and self-adjusting front disc brakes are standard on all models.

The front outlet tube of the master cylinder is connected to the hydraulic system control valve and then to the rear brakes. This is referred to as the secondary system. The rear outlet tube is connected to the control valve and to the front brakes. This system is referred to as the primary system. No residual pressure valves are used in the master cylinder outlets.

During normal operation, the fluid level in the master cylinder will rise during brake operation and fall during release. It is also expected that the fluid level will decrease with brake pad wear. In addition, a trace of brake fluid on the booster shell below the master cylinder mounting flange will often be found as a result of the normal lubricating action of the master cylinder

bore and seal. All of these conditions are considered normal and are not indications the master cylinder needs service.

Two types of master cylinders were used by Chrysler Corporation; 1) a cast iron master cylinder with built-in reservoir and separate proportioning valve and, 2) a master cylinder with a pressed on plastic reservoir. The body of the two-piece master cylinder is made of anodized aluminum and the reservoir is made of nylon. Both compartments of the reservoir are interconnected to permit equalization of the fluid level. However, a sufficient quantity of fluid is retained in the reservoir of the unaffected system to permit operation of that half of the master cylinder even if the other half of the reservoir is drained due to a hydraulic leak.

Use extra care when servicing aluminum master cylinders not to cross thread brake line fittings and do not overtighten any threaded connection.

In the event of a front brake system malfunction the proportioning valve with a bypass feature allows full hydraulic pressure to the rear brake system.

Disassembly and Assembly

The manufacturer does not recommend that either the cast iron or the aluminum master cylinder be overhauled, but replaced only. Do not attempt to hone the bore of the aluminum master cylinder or the hard anodized surface will be removed.

On the aluminum master cylinders, the plastic reservoir may be replaced using the following procedure:

1. Clean the outside of the master cylinder and remove the caps. Drain and discard remaining brake fluid.

2. Hold the master cylinder in a soft-jaw vise and grasp the plastic reservoir. Firmly rock reservoir from side to side to and remove it from the master cylinder housing. Don't pry the reservoir off with a tool that could damage the plastic body.

3. Remove and discard the reservoir grommets from the master cylinder body.

4. To install, lubricate the new

Chrysler aluminum master cylinder

Removing plastic reservoir from master cylinder housing

grommets with brake fluid and install in the master cylinder body.

5. Place the reservoir in position. Make sure it is positioned properly and that the lettering can be read from the left side of the master cylinder. Install by rocking the reservoir while pressing down. Seat the reservoir until the bottom of the reservoir touches the top of the grommets.

Brake Booster Service

Chrysler Corporation models covered here are equipped with vacuum boosters.

Under normal operating conditions, with brakes released, a vacuum suspended booster operates with vacuum on both sides of its diaphragm (or both diaphragms in a tandem diaphragm unit). When the brakes are applied, air at atmospheric pressure is admitted to one side of the diaphragm (or both diaphragms in a tandem diaphragm unit) to provide the power assist.

Brake boosters used by Chrysler Corporation are not repairable and if defective, the booster must be replaced as a unit, including the check valve. Do not remove the check valve.

Brake Booster Vacuum Pump

On gasoline engine vehicles, engine vacuum is used to power the vacuum booster brake. On diesel engines, there is not enough vacuum available for vacuum booster brake operation.

On diesel engine vehicles, vacuum is supplied from a pump. On Chrysler Corporation vehicles equipped with Cummins Turbo Diesels, the vacuum pump and power steering pump is one assembly which is driven from a common shaft from the front gear train. To service either pump, the complete assembly must be removed from the front gear housing.

In addition, these vehicles will have an engine warning light panel on the dash which contains 5 warning indicator lights: Brake, Water In Fuel, Wait To Start, Anti-Lock and Low Fuel. The Brake light is connected to a sen-

sor that monitors vacuum in the brake booster system. The Brake light when lit indicates low vacuum. If this light comes on, the brake system must be serviced.

NOTE: The brake light will also be activated when the parking brake is on or there is a hydraulic brake failure.

The vacuum pump provides vacuum for the brake booster and dash controllers. The vacuum sensor is mounted under the left hood hinge in the engine compartment. Vacuum is supplied by a hose Teed off the check valve in the brake booster. The sensor will activate the brake light on the warning light panel in 10 seconds or less when the vacuum drops to 8.5 in. Hg or less in the brake system.

Removal and Installation

1. Remove the vacuum pump and power steering pump assembly by removing the 2 bolts which should need an 18mm wrench.
2. Clean the gasket from the engine rear cover.
3. Install the pump assembly with a new gasket. Torque the bolts to 57 ft. lbs.

Disassembly and Assembly

1. Before starting pump disassembly, make a pin 2 in. long and 0.312 in. diameter. Use an 8mm bolt or a piece of drill rod. This pin must be hard so make it from a 10.9 grade metric bolt or at least an SAE Grade 8 capscrew.
2. Insert the pin into the pump shaft and screw a M14-2mm threaded capscrew in against the pin.
3. Tighten the capscrew against the pin to draw off the gear/eccentric/bearing assembly off of the power steering pump shaft.
4. Inspect the gear for excessive wear or damage. If the gear/eccentric is not damaged, do not separate them. If the gear is damaged, use a press to press the eccentric out of the gear. Use a flat plate over the new gear and press it onto the eccentric until it bottoms.
5. Inspect the bearing, turning it by hand. If the bearing looks good, and feels smooth to turn, do not separate them. If the bearing/eccentric is bad, press the eccentric out of the bearing, using the appropriate size socket or tool that will press only on the inner race of the bearing. Press it on until it bottoms.

6. With a 15mm wrench, remove the 4 nuts and separate the power steering pump from the vacuum pump housing. Remove the two short pushrods from the housing. Inspect the pushrods. They should move smoothly, but should not move side to side.

Power steering and vacuum pump on Cummins diesel engine

Message center includes low vacuum and antilock system warning lights

Vacuum sensor under the left hood hinge is supplied by line from booster check valve

Removing power steering and vacuum pump assembly from engine's gear drive

Fabricate pin for pressing off drive gear

7. With a 10mm wrench, remove the diaphragm assemblies from the housing. If the diaphragms are bad, they must be replaced as a unit. Remove and discard the O-rings from the center bore and push rod bores.

8. Clean all parts and dry with compressed air.

Insert pin, tighten cap screw against pin to draw gear assembly from pump shaft

9. Install the two spacers on the studs on the back of the power steering pump.

10. Install the vacuum pump housing onto the power steering pump using a new O-ring lubricated with engine oil. Install the four retaining nuts and with a 15mm wrench, torque to 18 ft. lbs.

11. Install the gear/eccentric/bearing assembly by pulling it onto the power steering shaft with a $\frac{3}{8}$ -18 thread cap screw with a flat washer threaded into the power steering pump shaft. Pull it on until it bottoms. Remove cap screw and washer.

NOTE: This is a press fit and will require a minimum of SAE Grade 8 cap screw for thread strength.

12. Lubricate the pushrods with engine oil and install then in the housing. Install new O-rings, also lubricated with engine oil.

13. With a 10mm wrench, install the

Remove the pushrods from the housing

Remove vacuum diaphragm assemblies, then O-rings

Use $\frac{3}{8}$ -18 Grade 8 cap screw to draw assembly onto pump shaft

Lube pushrods and O-rings with engine oil at assembly

diaphragm assemblies. Torque to 7 ft. lbs.

14. Install the assembly to the engine with new gaskets. Torque bolts to 57 ft. lbs.

Combination Valve

All models have a hydraulic system control valve in the brake system. The valve is usually mounted on the frame rail below the master cylinder. The control valve assembly in B-150 and B-250 models combines a brake warning switch with a hold-off and proportioning valve assembly. A brake warning switch and hold-off valve assembly are combined and used on B-350 models. Hold-off and Proportioning valves are used because of different braking characteristics between disc and drum brakes.

A height sensing proportioning valve regulates the front to rear braking balance based upon vehicle load conditions. The valve senses vehicle loads through variations in rear suspension height. With a light load on the rear axle, the valve reduces hydraulic pressure to the rear brakes. As the load increases, more hydraulic pressure is released to the rear brakes.

Combination warning switch/hold-off/proportioning valve assembly—Typical

Brake warning switch/hold-off valve

HOLD-OFF VALVE

The hold-off valve section of the combination valve holds off pressure to the front disc brakes to allow the rear drum brake shoes to overcome the return springs and begin to contact the drums. This valve keeps the output pressure to the front brakes in the 3-30 psi range until the hold-off pressure is reached (117 psi) and then blends back to give full output pressure to the front brakes under heavy brake applications. This feature helps keep the front brakes from locking under light pedal applications when driving on icy surfaces. The hold-off valve has no effect on front brake pressure during hard stops.

Checking the Hold-Off Valve

A visual check will show that the valve stem extends slightly when the brakes are applied and retracts when the brakes are released.

In case of a hold-off valve malfunction, remove the valve and install a new combination valve assembly.

BRAKE WARNING SWITCH

The hydraulic brake system is split. The front brakes are part of one system and the rear brakes are part of the other. Both systems are routed through, but hydraulically separated by the pressure differential switch. The function of this switch is to alert the driver to a malfunction in one of the hydraulic systems. Since the brake system is split, a failure in one part of

the brake system does not result in failure of the entire hydraulic brake system.

The brake warning light on the instrument panel will come on if one of the brake systems should fail after the brake pedal is depressed. The warning light switch is the latching type. It will automatically recenter itself after the repair is made and the pedal is depressed.

The instrument panel bulb can be checked each time the ignition switch is turned to **ON**, **START** or the parking brake is set.

Checking the Brake Warning Switch Unit

The brake warning light is lit only when the parking brake is applied with the ignition key turned **ON**. The same light will also illuminate should one of the two service brake systems fail.

To test the service brake warning system, raise the car on a hoist and open a wheel cylinder bleeder while a helper depresses the brake pedal and watches the warning light. If the light fails to light, check for a burned out bulb, disconnected socket, or a broken or disconnected wire at the switch. If the bulb is not burned out and the wire continuity is uninterrupted check the service brake warning switch operation with a test lamp between the switch terminal and a voltage source.

If the light still fails to light, disconnect the brake tubes from the valve assembly and install a new valve assembly. If a new is installed, bleed the system. The warning switch is not serviced separately. Do not remove the switch or attempt to repair.

After repairing and bleeding the brake system applying the brakes with moderate force will hydraulically recenter the valve's piston and automatically turn off the warning light. Do not disassemble to reset the piston.

Caliper Service

Chrysler Corporation calipers are one-piece castings with the inboard side containing the piston bore. A square cut rubber seal is located in a groove in the piston bore which provides the hydraulic seal between the piston and the cylinder wall.

As the brake pedal is pressed, hydraulic pressure is applied against the piston. This pressure pushes the inboard brake lining against the inboard braking surface of the rotor. As the force increases against the rotor, the caliper assembly moves inboard and provides a clamping action on the rotor.

When brake pressure is released,

Caliper assembly—typical

Remove piston seal without scratching bore

Clean up bore with light honing

Lubricate piston seal with brake fluid and install

the piston seal returns to its normal position, pulling the piston back into the caliper bore. This creates a running clearance between the inner brake lining and rotor.

Disassembly and Assembly

1. Chrysler Corporation does not recommend using air pressure to remove the piston from the caliper due to the possibility of personal injury. Their suggested procedure is to remove the caliper from its vehicle mount, remove the outboard shoe and support the caliper on top of the control arm on shop towels to absorb brake fluid. Carefully depress the brake pedal and allow hydraulic pressure to push the piston out of the bore.

NOTE: The brake pedal will fall away when the piston has passed the bore opening. Prop the brake pedal to any position below the first inch of pedal travel to prevent loss of brake fluid. If both front caliper pistons are to be removed, disconnect the flexible brake line at the frame bracket after removing the first piston. Plug the brake line to remove the piston from the opposite caliper.

2. Remove the flexible brake line from the caliper.

3. Mount the caliper in a soft-jaw vise. Do not use too much pressure or the bore will be distorted and the piston will bind.

4. Remove the dust boot and, using a small, pointed wooden stick, work the piston seal out of its groove in the caliper bore. Do not use any metal tool which might nick or scratch the bore. Discard the seal.

5. Clean all parts well using alcohol and blow dry. Inspect the piston bore for scoring or pitting. Install a new piston if it is pitted, scored or the plating is worn. Some pistons are plastic. Bores that show light scratches can be cleaned with fine crocus cloth. Deeper scratches may need to be honed.

NOTE: The bore must not be honed more than 0.002 in. over-size (only 0.001 in. oversize on Caravan, Voyager and Town & Country models). Measure the bore accurately before honing. If the bore does not clean up within this specification, a new housing must be installed. Black stains on the piston are caused by the piston seal and will do no harm.

6. Clean all parts well, dip the new piston seal in brake fluid and install in the bore. Position the seal at one area at a time and, using fingers, gently work the seal into the groove.

7. Coat the new piston boot with brake fluid leaving a generous amount inside the boot. Position the boot on the piston and install the piston into the bore, pushing it past the piston seal until it bottoms in the bore.

8. Position the dust boot and with a circular driver, seal into the caliper.
9. Install the flexible brake hose with new seals.

Wheel Cylinder Service

The rear brakes are drum type with internal expanding shoes. The rear brakes are of the single anchor type, mounted to the same anchor and actuated by 1 wheel cylinder. The wheel cylinder has 2 pistons. Brake adjustments are automatic and are made during reverse brake applications.

Wheel cylinders may need reconditioning or replacement whenever the brake shoes are replaced or when required to correct a leak condition. Leaks which coat the boot and the cylinder with fluid, or result in a dropped reservoir fluid level, or dampen and stain the brake linings are dangerous. Such leaks can cause the brakes to grab or fail and should be immediately corrected. A leakage, not immediately apparent, can be detected by pulling back the cylinder boot. A small amount of fluid seepage dampening the interior of the boot is normal. However, a dripping boot is not. Unless other conditions causing a brake to pull, grab or drag become obvious, the wheel cylinder is suspect and should and should be included in general reconditioning.

Cylinder binding may be caused by rust, deposits, grime, or swollen cups due to fluid contamination, or by a cup wedged into an excessive piston clearance.

Hydraulic system parts should not be allowed to come into contact with oil or grease, neither should those be handled with greasy hands. Even a trace of any petroleum based product is sufficient to cause damage to the rubber parts.

Disassembly and Assembly

1. Remove the brake bleeder screw.
2. Remove the dust boots, allow any brake fluid to drain out.
3. Remove the pistons, seals and inner spring.
4. Inspect the bore for scoring and corrosion. The inside of the bore may be cleaned with fine crocus cloth. If bore is scored, replace cylinder. Black stains on the cylinder walls are caused by the piston cups and will not impair operation of the cylinder. Clean the cylinder with alcohol or brake fluid.
5. Lubricate the seals with brake fluid and install. Cup lips should always face inward. Install the spring assembly and seals.

Rear wheel cylinder for 11 and 12 inch brakes—typical

6. Carefully install the pistons and dust boots.
7. Install the bleeder screw.

Anti-Lock Braking Systems

Despite advances in brake design over the years, even the best systems in use can still lock up during certain road conditions, such as wet road surfaces. When the brakes lock up, the driver can lose control of the vehicle, because a locked wheel cannot absorb any cornering or lateral forces, and steering is lost. It is impossible to brake to a maximum and at the same time steer the vehicle when the front wheels are locked. If the back wheels are locked the vehicle will become unstable and start to slide.

While many different ways have been tried over the years to solve this problem, mechanical sensors could not provide sufficient information about wheel rotation speed and mechanical control units could not operate the brakes fast enough to prevent brake lockup.

The growth of the electronics industry has allowed small computers (microprocessors) to be reduced in both size and cost. Coupled with fast reacting electronic sensors, anti-lock braking has become more reliable with widespread application.

REAR WHEEL ANTI-LOCK BRAKE SYSTEM

Chrysler Corporation's Rear Wheel Antilock brake system (RWAL) is designed to prevent rear wheel lockup under heavy braking conditions. Anti-lock braking allows a vehicle to stop without locking the wheels and therefore maintains directional stability.

The RWAL system uses a standard master cylinder and booster arrangement with a vertical split hydraulic circuit. An electronic control module,

rear wheel speed sensor, and a dual solenoid control valve (hydraulic valve) are the major components added to this system. No hydraulic pumps are used. Braking pressure comes directly from pushing on the brake pedal.

RWAL connection locations—typical

RWAL electronic brake control module—typical

RWAL electronic brake control module pin locations

18 BRAKES DOMESTIC

The system will provide vehicle stability by allowing at least one rear wheel to remain unlocked. Since the system works on the rear wheels only it is possible to lock the front wheels. In addition, the system benefit is

somewhat limited when a 4WD vehicle is in the 4WD mode.

The system utilizes an amber antilock warning lamp in the instrument panel along with the standard red brake warning light. These two

lights work together to notify the driver the driver that the system is working correctly. These lamps are also used to blink fault codes for system diagnosis.

Test Step	What to do	Condition	Yes	No
TEST 1 VISUAL INSPECTION				
1.1	Inspect RWAL connectors and ground for defects and good connections	Are connectors free of defects and connected properly?	Go to Test 2	Repair or connect terminals as required
TEST 2 SYSTEM SELF CHECK				
2.1	Turn ignition switch to run position	Both lamps illuminate for 2 seconds then go out as system performs self check	Go to Test 3	Choose another condition
		Antilock and brake lamp stay on	Go to Test 6	Choose another condition
		Antilock lamp off and will not self check, brake lamp checked OK	Go to Test 7	Choose another condition
		Brake lamp on, antilock lamp off and does self check	Go to Test 8	Choose another condition
		Antilock and brake lamps flashing	Go to Test 9	Choose another condition
		Brake lamp off, antilock lamp on, antilock lamp does self check	Go to Test 10	Choose another condition
TEST 3 CHECKING SENSOR OUTPUT AND PHYSICAL CONDITION				
3.1	Apply service brakes and check stop lights	Stop lamps illuminate	Go to Test 3.2	Repair stop lamp circuit
3.2	Remove sensor from differential and inspect exciter ring for damage	Exciter ring in good condition	Reinstall sensor. Go to Test 3.3	Replace exciter ring and retest system
3.3	Lift rear wheels, start engine, run wheels at 5 mph. Make sure vehicle is properly positioned on hoist or jack stands. WARNING: STAY CLEAR OF ROTATING WHEELS. Using a voltmeter set on 2 volt AC scale and connect between B01 PK and B02 LG/OR* wires of the sensor connector	Is voltage 650 MV (RMS) or greater?	Go to Test 5	Go to Test 3.4
3.4		Has sensor been replaced?	Go to Test 3.5	Replace sensor and go to Test 3.3
3.5	Disconnect 14 way module connector. Disconnect sensor connector and connect an ohmmeter between B01 RD/VT* wire in module connector and B01 PK wire in sensor connector	Is there continuity?	Go to Test 3.6	Repair open circuit
3.6	Connect an ohmmeter between B01 RD/VT* wire in module connector and ground	Is there continuity?	Repair circuit for a short to ground	Go to Test 3.7
3.7	Connect an ohmmeter between B02 WT/VT* wire in module connector and B02 LG/OR wire in sensor connector	Is there continuity?	Repair circuit for an open circuit	Go to Test 3.8
3.8	Connect an ohmmeter between B02 WT/VT* wire in module connector and ground	Is there a short to ground?	Repair circuit for short to ground	Go to Test 4

Test Step	What to do	Condition	Yes	No
TEST 4 CHECKING SENSOR GAP				
4.1	Remove sensor from differential. Measure height of sensor pole piece from mounting face of sensor (should be 1.07"–1.08"). Measure top of exciter ring teeth from sensor mounting face on differential (should be 1.085"–1.12"). Subtract measurements as shown to obtain sensor gap. Gap must be a minimum of 0.005" and a maximum of 0.05"	Was gap within specifications?	Go to Test 5	Go to Test 4.2
4.2	Look at sensor measurement from Test 4.1 (should be 1.07"–1.08")	Was sensor measurement within specifications?	Repair differential and retest system	Replace sensor and retest system
TEST 5 CHECKING FOR BRAKE MECHANICAL PROBLEMS				
5.1	Check rear brakes for mechanical problems such as grabbing, locking or pulling	Are the rear brakes functioning properly?	Replace module and retest system	Repair mechanical problem and retest system
TEST 6 CHECKING THE DIAGNOSTIC CONNECTOR GROUND				
6.1	Locate the black 2-way diagnostic connector below RWAL module. Connect a jumper wire between the diagnostic connector and ground	Is there a flashout code?	Go to Test 11	Go to 6.2
6.2	Turn ignition off. Disconnect 14-way connector from module and connect an ohmmeter between the BK* in the 14-way connector and the BK* in the 2-way diagnostic connector	Is there continuity?	Go to Test 6.3	Repair open circuit and retest system
6.3	Check brake fluid level in master cylinder reservoir	Is brake fluid level correct?	Go to Test 6.4	Find and repair leak and retest system
6.4	Reconnect 14-way module connector. Disconnect connector from the pressure differential switch. Turn ignition to run position	Do both antilock lamp and brake lamp stay on?	Go to Test 6.5	Check brake system for air in lines or mechanical damage
6.5		Does the vehicle have a diesel engine?	Go to Test 6.6	Go to Test 6.7
6.6	Disconnect harness connector from vacuum warning switch. Turn the ignition switch to the run position	Do both lamps stay on?	Go to Test 6.7	Check complete vehicle vacuum system, repair as required and retest system
6.7	Disconnect 14-way module connector. Turn ignition switch to the run position	Are both antilock lamp and brake lamp off?	Go to Test 6.8	Choose another condition
		Antilock lamp on, brake lamp off	Repair AT1 orange wire for short to ground between module and antilock lamp	Repair short to ground in differential switch sensor wiring, B01 PK and B02 LG/OR
6.8	Remove and inspect antilock fuse	Is fuse open?	Check and repair all circuits fuse is protecting. Replace fuse	Go to Test 6.9

18 BRAKES DOMESTIC

Test Step	What to do	Condition	Yes	No
TEST 6 CHECKING THE DIAGNOSTIC CONNECTOR GROUND				
6.9	Connect a voltmeter between pin 3 RD/YL wire of 14-way module connector and ground	Is voltage greater than 9 volts?	Go to Test 6.10	Repair the D1 RD/YL wire for an open
6.10	Remove and inspect the stop lamp fuse.	Is the fuse open?	Check and repair all circuits fuse is protecting for shorts and replace fuse	Go to Test 6.11
6.11	Connect a voltmeter between pin 9 of the 14-way module connector and ground	Is voltage greater than 9 volts?	Replace module and retest system	Repair the D3B PK/DB* wire for open circuit.
TEST 7 CHECKING MODULE GROUND AND POWER				
7.1	Make sure module connector is fully-plugged into module	Is connector plugged in?	Go to Test 7.2	Plug connector in and retest system
7.2	Disconnect battery and 14-way module connector. With an ohmmeter set on 200 ohm scale, check resistance between pin 10 BK/LG wire on the 14-way harness connector and ground	Is resistance less than 1 ohm?	Go to Test 7.3	Repair H40 BK/LG for an open or damaged circuit
7.3	Remove and inspect antilock lamp fuse	Is fuse open?	Check and repair all circuits fuse is protecting for shorts and replace fuse	Go to Test 7.4
7.4	Connect battery and turn ignition to run position. With a voltmeter set on 20 volt DC scale, check voltage between Pin 2 Orange wire of the 14-way module connector and ground	Is voltage less than 9 volts?	Go to Test 7.5	Replace the module and retest system
7.5	Check antilock bulb	Is bulb open?	Replace bulb and retest system	Repair AT1 orange wire for open circuit between pin 2 and fuse
TEST 8 CHECKING PARKING SYSTEM AND MODULE				
8.1	Turn ignition to run position. Pull lever to release parking brake	Does the brake lamp go off?	Disregard failure, retest antilock and brake lamp for 2 second self check	Go to Test 8.2
8.2	Pull park brake release lever with one hand and pull pedal up with other hand	Did brake lamp go off	Repair park brake mechanism or switch	Go to Test 8.3
8.3	Disconnect black 1-way park brake switch connector	Did brake lamp go off	Adjust or replace park brake switch and retest system	Go to Test 8.4
8.4	Disconnect 14-way module connector	Did brake lamp go off?	Replace module and retest system	Repair P5 BK/GY wire for a short to ground

Test Step	What to do	Condition	Yes	No
TEST 9 CHECKING FOR INTERMITTENT PROBLEMS				
9.1	Disconnect 14-way module connector. With a voltmeter set on 20 volt DC scale, check voltage between pin 3 RD/YL wire on the 14-way module connector and ground. Turn ignition to run position and shake the instrument panel harness	Is voltage steady at 9 volts?	Go to Test 9.2	Repair D1 RD/YL for open circuit
9.2	Disconnect battery, set ohmmeter on 200 scale and connect between pin 12 BK wire of the 14-way module connector and ground, then shake the instrument panel harness	Is resistance 100K or greater and steady?	Go to Test 9.3	Repair DK/BK/* wire for a short to ground
9.3	With ohmmeter set on 200 ohm scale, connect between Pin 10 BK/LG wire of the 14-way module connector and ground, then shake instrument panel harness.	Is resistance steady at 1 ohm?	Replace module and retest system	Repair open circuit in H40 BK/LG
TEST 10 CHECKING FOR OPEN OR DISCONNECTED PARK BRAKE SWITCH CONNECTOR				
10.1	Make sure the P5 BK/GY wire at the park brake switch is connected	Is P5 wire connected to park brake switch?	Go to Test 10.2	Connect and retest system
10.2	Disconnect park brake switch connector. Disconnect message center black 6-way connector. Connect an ohmmeter between P5 BK/BY wire in both connectors	Is there continuity?	Go to Test 10.3	Repair P5 BK/GY wire for open circuit
10.3	Inspect instrument cluster printed circuit board for damage	Is printed circuit board damaged?	Replace printed circuit board	Replace brake warning lamp bulb
TEST 11 FLASHCODES				
11.1	Connect a jumper wire between the diagnostic connector and ground. Count the flashes including the long flash that starts the flash code count. Choose the proper condition	Antilock lamp and brake lamp flash 1 time	Go to Test 12	
		Antilock lamp and brake lamp flash 2 times.	Go to Test 13	
		Antilock lamp and brake lamp flash 3 times.	Go to Test 14	
		Antilock lamp and brake lamp flash 4 times.	Go to Test 15	
		Antilock lamp and brake lamp flash 5 times.	Go to Test 16	
		Antilock lamp and brake lamp flash 6 times.	Go to Test 17	
		Antilock lamp and brake lamp flash 7 times.	Go to Test 18	
		Antilock lamp and brake lamp flash 8 times.	Go to Test 19	
		Antilock lamp and brake lamp flash 9 times.	Go to Test 20	
		Antilock lamp and brake lamp flash 10 times.	Go to Test 21	
		Antilock lamp and brake lamp flash 11 times.	Go to Test 22	

18 BRAKES DOMESTIC

Test Step	What to do	Condition	Yes	No
TEST 11 FLASHCODES				
		Antilock lamp and brake lamp flash 12 times.	G to Test 23	
		Antilock lamp and brake lamp flash 13 times.	G to Test 24	
		Antilock lamp and brake lamp flash 14 times.	G to Test 25	
		Antilock lamp and brake lamp flash 15 times.	G to Test 26	
		Antilock lamp and brake lamp flash 16 times.	G to Test 27	
TEST 12 ONE FLASH				
12.1	One flash code should not occur. Perform flashcode procedure several times	Are you still getting code 1?	Go to Test 5	Go to Test 11
TEST 13 TWO FLASHES				
13.1	Disconnect battery and 14-way module connector. Set an ohmmeter on 200 ohm scale and connect between pin 1 LG wire of the 14-way module connector and ground	Does the circuit have over 6 ohms?	Go to test 13.2	Replace the module and retest system
13.2	Disconnect valve harness connector from valve connector. Connect an ohmmeter between B09 GY/WT of harness connector and ground	Is resistance greater than 1 ohm?	Repair B09 GY/WT wire for an open circuit or high resistance. Check for contaminated or loose connector pins and retest system	Go to Test 13.3
13.3	Connect an ohmmeter between IS1 LG/* and B09 GY/WT wires in the 4-way black valve connector	Does circuit have over 6 ohms?	Replace antilock valve and retest system	Repair the IS1 LG/* for open circuit from valve to computer module and retest system
TEST 14 THREE FLASHES				
14.4	Disconnect battery. Remove 14-way module harness connector from module. Set ohmmeter on 200 ohm scale and connect to pin 8 DS1 WT/BR and ground	Does circuit have over 3 ohms?	Go to Test 14.2	Replace module and retest system
14.2	Disconnect the 4-way valve harness connector. Connect an ohmmeter between DS1 WT and B09 GY/NT wires in valve connector	Does circuit have over 3 ohms?	Replace antilock valve and retest system	Repair DS1 WT wire for open between module connector and valve connector

Test Step	What to do	Condition	Yes	No
TEST 15 FOUR FLASHES				
15.1	Disconnect the 4-way valve harness connector from valve connector. Set ohmmeter on 20K scale and connect between VS1 LB wire in valve body and ground	Is resistance greater than 10K ohms?	Go to Test 15.2	Replace the antilock valve and retest system
15.2	Connect an ohmmeter between VS1 LB and B09 GY/WY wires in the valve connector	Is resistance greater than 10K ohms?	Go to Test 15.3	Replace the antilock valve and retest system
15.3	Disconnect battery. Disconnect the 14-way module harness connector from module. Set ohmmeter on 200K scale and connect to pin 11, VS1 LB of 14-way connector and ground	Is resistance greater than 100K ohms?	Replace module and retest system	Repair VS1 LB wire for a short to ground between valve and module. Retest system
TEST 16 FIVE FLASHES				
16.1	Did the failure occur in 2 wheel drive mode?		Go to Test 16.2	Go to Test 16.3
16.2	Disconnect 14-way module connector from module to deactivate antilock system. Drive the vehicle in 2 wheel drive mode and make normal and safe stops to determine the condition of the rear brakes	Are the brakes functioning normally?	Replace the antilock valve and retest system	Repair rear brakes and retest system
16.3	Disconnect 14-way module connector from module. Turn ignition key to run position. Shift into 4 wheel drive. Set a voltmeter to 20 vdc and connect between pin 4, X4 LG/BR wire and ground	Is voltage greater than 1 volt?	Repair X4 wire for an open or 4 wheel drive indicator switch. Retest system	Replace antilock valve and retest system
TEST 17 SIX FLASHES				
17.1	Recheck flashcode after driving vehicle	Antilock light and brake light flash 6 times	Go to Test 17.2	Go to Test 11
17.2	Disconnect battery. Disconnect 14-way module connector. Set ohmmeter on 200 ohm scale and connect between pin 13, B02 WT/VT and pin 14, B01 RD/VT of harness connector. Shake antilock wiring harness from differential to module	Is resistance constant at 1000–2000 ohms?	Go to Test 17.3	Repair circuit. Retest system
17.3	Remove sensor from the differential and inspect for build up of metal chips on sensor pole piece	Are metal chips present?	Drain and clean differential. Check exciter ring for broken or chipped teeth. Retest system	Go to Test 17.4
17.4	Look into sensor hole in differential and rotate exciter ring and check for damage (missing or bent teeth)	Is exciter ring intact?	Go to 17.5	Replace exciter ring. Retest system
17.5	Reinstall sensor. Disconnect 2-way RWAL sensor connector. With a voltmeter on 2 volt scale, connect between B01 PK and B2 LG/OR wires of sensor connector. Raise rear wheels off floor and run at 5 mph. WARNING: STAY CLEAR OF ROTATING WHEELS	Is voltage greater than 650 MV and steady?	Replace module. Retest system	Replace sensor. Recheck sensor output. Retest system

18 BRAKES DOMESTIC

Test Step	What to do	Condition	Yes	No
TEST 18 SEVEN FLASHES				
18.1	Disconnect 4-way valve harness connector from valve connector. Connect an ohmmeter between IS1 LG/* and B09 GY/WT wire in valve connector	Is resistance less than 3 ohms?	Replace antilock valve. Retest system	Go to Test 18.2
18.2	Disconnect battery. Disconnect 4-way valve harness connector from valve connector. Disconnect 14-way module harness connector from module. Set ohmmeter on 20K ohms scale and connect between Pin 1, IS1 LG/* wire in harness connector and ground	Is resistance greater than 20K ohms?	Replace module. Retest system	Repair IS1 LG/* for a short between antilock valve and module. Retest system
TEST 19 EIGHT FLASHES				
19.1	Disconnect 4-way valve harness from valve connector. Set ohmmeter on 200 ohm scale and connect between DS1 WT and B09 GY/WT wires in valve connector	Is resistance less than 1 ohm?	Replace antilock valve. Retest system	Go to Test 19.2
19.2	Disconnect battery. Disconnect 4-way valve connector. Disconnect 14-way module connector. Set ohmmeter on 20K ohm scale and connect between pin 8, DS1 WT/BR and ground	Is resistance greater than 20K ohms?	Replace module	Repair DS1 WT/BR for a short to ground between antilock valve and module. Retest system
TEST 20 NINE FLASHES				
20.1	Disconnect 2-way sensor harness connector from sensor on differential housing. Set ohmmeter on 20K scale and connect to B01 PK and B02 LG/OR wire on sensor	Is resistance greater than 2500 ohms?	Replace sensor. Recheck resistance. Make sure seal is in place between sensor and connector. Retest system	Go to Test 20.2
20.2	Reconnect sensor harness making sure seal is in place. Disconnect battery. Disconnect 14-way module connector. Connect an ohmmeter between pin 13, B02 WT/VT and pin 14, B01 RD/VT wires in module harness connector	Is resistance greater than 2500 ohms?	Repair B02 WT/VT and B01 RD/VT for open circuits between the module and sensor. Retest system	Replace computer module. When reconnecting sensor, make sure seal is in place. Retest system
TEST 21 TEN FLASHES				
21.1	Set ohmmeter on 20K ohm scale. Disconnect 2-way sensor connector from sensor on differential. Connect an ohmmeter between B01 PK and B02 LG/OR wires on sensor	Is resistance less then 1000 ohms?	Replace sensor. Recheck resistance. Make sure seal is in place between sensor and connector. Retest system	Go to Test 21.2

Test Step	What to do	Condition	Yes	No
TEST 21 TEN FLASHES				
21.2	Disconnect battery. Disconnect 14-way module. Connect an ohmmeter between pin 14, B01 RD/VT and ground	Is resistance greater than 20K ohms?	Go to Test 21.3	Repair B01 RD/VT circuit between the module and sensor. When reconnecting sensor, make sure seal is in place . Retest system
21.3	Connect an ohmmeter between pin 13, B02 WT/VT and pin 14 B01 RD/VT wire in module harness connector	Is resistance greater than 20K ohms?	Replace module. Retest system	Repair B01 RD/VT and B02 WT/VT circuit. When reconnecting sensor, make sure seal is in place . Retest system
TEST 22 ELEVEN FLASHES				
22.1	Recheck flash code after driving vehicle at 35 mph or greater.	Antilock light and brake light flash 11 times	Go to Test 22.1	Go to Test 11
22.2	Apply vehicle service brakes and check vehicle stop lights	Are stop lights operating correctly?	Go to Test 22.3	Repair the stop lamp circuit. Retest system
22.3	Turn ignition switch off. Disconnect 14-way module connector from module. Connect a voltmeter between pin 7, D4 WT of harness connector and ground while stepping on brake pedal	Is voltage less than 9 volts?	Repair D4 WT for open circuit between stop light switch and module. Retest system	Check 4-way flasher, directional wiring, and feedback through stop light circuit. Major Components

The system continually monitors rear wheel speed with a sensor mounted on the rear axle. A toothed exciter ring is press fit onto the differential case next to the differential ring gear and provides a signal for the sensor. When the teeth on the exciter ring pass the sensor pole piece, an AC voltage is induced in the sensor circuit with a frequency proportional to the average rear wheel speed. In the event of an impending lockup condition during braking, the RWAL modulates hydraulic pressure to the rear brakes. This inhibits rear wheel lockup.

The electronic brake control module is located behind the glove box on most models. The control module monitors the rear wheel speed and controls the dual solenoid valve.

The control module determines if the rear wheels are decelerating too quickly and sends a signal to the dual solenoid hydraulic valve to prevent rear wheel lockup. The control module also performs a system self check every time the ignition key is turned ON.

The dual solenoid hydraulic valve is located between the rear brakes and the proportioning valve and is attached on the left frame rail near the rear axle.

Under normal conditions, the valve will allow brake fluid to flow freely between the master cylinder and the rear brakes. Once antilock braking begins the control module will trigger the valve to either isolate or reduce pressure to the rear wheels.

The electronic control module has the capability of generating and storing fault codes. Only one code can be stored and shown at any one time. Also, if a fault code is generated the electronic control module will retain the code even after a key OFF condition.

If a problem is detected the electronic control module will illuminate the amber antilock brake warning lamp and set a fault code. When a fault code is set the red brake warning lamp will also be lit. To determine what the fault code is, momentarily ground the RWAL diagnostic connector and count the flashes of the amber antilock warning lamp. The initial flash will be a long flash followed by a number of short flashes. The long flash indicates the beginning of the fault number sequence and the short flashes are a continuation of that sequence. Count the long flash with the short flashes to have an accurate fault code count.

To clear a fault code disconnect the control module connector from the module or disconnect the battery for at least five seconds. During system re-

test, wait 30 seconds to make sure the fault code does not reappear.

Removal and Installation

RWAL SPEED SENSOR

1. Raise and safely support vehicle.
2. Remove sensor hold down-bolt.
3. Remove sensor shield and sensor from differential by pulling sensor out of differential.
4. Disconnect wiring from sensor.
5. To install, connect wiring to sensor. Be sure the seal is in place between the sensor and wiring connector.
6. Install the sensor into the differential housing with a new O-ring.
7. Install sensor shield.
8. Install sensor hold down bolt. Torque to 170-230 inch lbs.
9. Lower vehicle.

ELECTRONIC BRAKE CONTROL MODULE

1. Remove the right side sill plate.
2. Remove the right side cowl cover.
3. Remove the three screws that attach electronic brake control module to side cowl.
4. Disconnect the wiring from the module.
5. When installing, connect the wiring first, then install the three mounting screws.
6. Install the right side cowl cover and sill plate.

DUAL SOLENOID HYDRAULIC VALVE

1. Raise and safely support vehicle.
2. Remove the brake lines from the valve.
3. Remove the 2 nuts that hold the valve to the frame.
4. Remove the valve from the frame and disconnect the wiring.
5. When installing, connect the wiring first, then install the valve. Torque the hold-down nuts to 16-25 ft. lbs.
6. Bleed the solenoid valve and the rear brakes.
7. Lower hoist.

self-adjusting front disc brakes are standard on all models.

The front outlet tube of the master cylinder is connected to the hydraulic system control valve and then to the rear brakes. This is referred the secondary system. The rear outlet tube is connected to the control valve and to the front brakes. This system is referred to as the primary system. No residual pressure valves are used in the master cylinder outlets.

During normal operation, the fluid level in the master cylinder will rise during brake operation and fall during release. It is also expected that the fluid level will decrease with brake pad wear. In addition, a trace of brake fluid on the booster shell below the master cylinder mounting flange will often be found as a result of the normal lubricating action of the master cylinder bore and seal. All of these conditions are considered normal and are not indications the master cylinder needs service.

Two types of master cylinders were used; 1) a cast iron master cylinder with built-in reservoir and separate proportioning valve and, 2) a master cylinder with a pressed on plastic reservoir. The body of the two-piece master cylinder is made of anodized aluminum and the reservoir is made of nylon. The two compartments of the reservoir are interconnected to permit equalization of the fluid level. However, a sufficient quantity of fluid is retained in the reservoir of the unaffected system to permit operation of that half of the master cylinder even if the other half of the reservoir is drained due to a hydraulic leak. There is another type of master cylinder used on vehicles equipped with anti-lock brakes. See anti-lock section.

Use extra care when servicing aluminum master cylinders not to cross thread brake line fittings and do not overtighten any threaded connection.

In the event of a front brake system malfunction the proportioning valve with a bypass feature allows full hydraulic pressure to the rear brake system.

Disassembly and Assembly

While the manufacturer does give overhaul procedures for the master cylinder, the manufacturer does not permit that either the cast iron or aluminum master cylinder be honed in an attempt to restore the surface. Replace the cylinder if the bore is corroded or if doubt exists about cylinder bore condition.

CAST IRON MASTER CYLINDER - EXCEPT ANTI-LOCK

1. Remove the cover and drain fluid. Examine cover seal for damage.

JEEP

Master Cylinder Service

Jeep uses a dual master cylinder which contains a double hydraulic cylinder with 2 fluid reservoirs and primary and secondary hydraulic pistons. The master cylinder is assisted by a vacuum booster. Hydraulic rear drum brakes with automatic adjusters and

2. Mount cylinder in vise and press in primary piston. Remove snapping.
3. Remove the primary piston and discard. It is serviced only as an assembly.
4. Apply a small amount of compressed air to secondary outlet while covering small ports at bottom of rear reservoir to ease secondary piston from bore.
5. Disassemble secondary piston. Discard seals, spring and retainer.
6. Inspect bore carefully, clean and dry with compressed air. Do not hone bore if scored. Replace the assembly.
7. Coat the cylinder bore and new piston assemblies with clean brake fluid. Assemble the secondary piston, making sure the seals are facing the proper direction. Assemble the retainer and return spring and insert assembly into the cylinder bore.
8. Install the primary piston into the bore, push in and install the snapping.
9. Bench-bleed the master cylinder before installation.

Use air pressure to remove secondary piston

Secondary piston components

Bleeding master cylinder—typical

ALUMINUM MASTER CYLINDER—EXCEPT ANTI-LOCK

1. Remove the reservoir cover, seal and drain fluid.
2. Mount the cylinder in a vise. Clamp vise jaws on one of the mounting ears so cylinder bore not be distorted.
3. Remove reservoir with a rocking motion. Remove the seal grommets.
4. Remove the cylinder snapping.
5. Remove the primary piston and discard. It is serviced only as an assembly.
6. Apply a small amount of compressed air to secondary outlet to ease secondary piston from bore.
7. Disassemble secondary piston. Discard seals, spring and retainer.
8. Inspect the cylinder check valve. Remove the valve snapping and replace the valve if necessary. The tube seats can also be replaced. Remove by forced a hardened self-tapping screw, then pry upwards using the proper tools to remove the seat.
9. Inspect bore carefully, clean and dry with compressed air. Do not hone bore if scored. Replace the assembly.
10. Coat the cylinder bore and new piston assemblies with clean brake fluid. Assemble the secondary piston, making sure the seals are facing the proper direction. Assemble the retainer and return spring and insert assembly into the cylinder bore.
11. Install the primary piston into the bore, push in and install the snapping.
12. Install new reservoir grommets into the cylinder body.
13. Turn reservoir upside down and place on flat surface. Press the master cylinder onto the reservoir with a rocking motion. Be sure it is fully seated.
14. Bench bleed the master cylinder before installation.

Brake Booster Service

Jeep models covered are equipped with vacuum boosters, except those equipped with the anti-lock brake system. Anti-lock master cylinder/power brake booster units are not repairable and must be replaced as a complete assembly.

Under normal operating conditions, with brakes released, a vacuum suspended booster operates with vacuum on both sides of its diaphragm (or both diaphragms in a tandem diaphragm unit). When the brakes are applied, air at atmospheric pressure is admitted to one side of the diaphragm (or both diaphragms in a tandem diaphragm unit) to provide the power assist.

Brake boosters used by Jeep are not repairable and if defective, the booster

Aluminum master cylinder

Aluminum master cylinder components

Installing the reservoir to the master cylinder body

must be replaced as a unit. The brake boosters used on different models of Jeeps are different sizes and are not interchangeable.

Combination Valve

All models have a hydraulic system control valve in the brake system. A combination proportioning valve/pressure differential switch is used on all models. Comanche series pickup trucks are equipped with a rear brake height sensing proportioning valve. The valve adjusts front-rear brake proportioning to maintain brake balance when the vehicle is loaded.

A dual purpose warning lamp is located in the instrument cluster. The primary function of this lamp is to alert the driver if a pressure differential exists between the front and rear brake hydraulic systems. The lamp also functions as an indicator to alert the driver when the parking brake is applied.

Caliper Service

Jeep calipers are one-piece castings with the inboard side containing the piston bore. A square cut rubber seal is located in a groove in the piston bore which provides the hydraulic seal between the piston and the cylinder wall.

As the brake pedal is pressed, hydraulic pressure is applied against the piston. This pressure pushes the inboard brake lining against the inboard braking surface of the rotor. As the force increases against the rotor, the caliper assembly moves inboard and provides a clamping action on the rotor.

When brake pressure is released, the piston seal returns to its normal position, pulling the piston back into the caliper bore. This creates a running clearance between the inner brake lining and rotor.

Disassembly and Assembly

1. Place shop towels under the caliper piston to protect it during removal. Apply a little compressed air to slowly ease the piston out of the bore.

2. Remove the dust boot and, using a small, pointed wooden stick, work the piston seal out of its groove in the caliper bore. Do not use a screwdriver or metal tool which might nick or scratch the bore. Discard the seal.

3. Clean all parts well using alcohol and blow dry. Inspect the piston bore for scoring or pitting. Install a new piston if it is pitted, scored or the plating is worn. Jeep does not recommend honing calipers or using any type of abrasives on the basis that abrasives will ruin the piston plating and cause it to corrode and bind. Replace the piston if damaged in any way.

4. Clean all parts well, dip the new piston seal in brake fluid and install in the bore. Position the seal at one area at a time and, using fingers, gently work the seal into the groove.

5. Slide the metal retainer part of the new dust boot over the open end of the piston. Pull the retainer rearward until the boot lip seats in the groove at the end of the piston. Push the metal retainer part of the boot forward until flush with the rim at the open end of the piston. Then snap boot folds in place. Finally, install the piston in the caliper bore with a twisting motion being careful not to unseal the piston seal.

6. Seal the metal retainer part of the dust boot in the caliper with a circular driver.

7. Install new mounting bushings in the caliper as required. Install bleeder screw if removed.

8. Install the flexible brake hose with new seals.

apparent, can be detected by pulling back the cylinder boot. A small amount of fluid seepage dampening the interior of the boot is normal. However, a dripping boot is not. Unless other conditions causing a brake to pull, grab or drag become obvious, the wheel cylinder is suspect and should and should be included in general reconditioning.

Cylinder binding may be caused by rust, deposits, grime, or swollen cups due to fluid contamination, or by a cup wedged into an excessive piston clearance.

Hydraulic system parts should not be allowed to come into contact with oil or grease, neither should those be handled with greasy hands. Even a trace of any petroleum based product is sufficient to cause damage to the rubber parts.

Disassembly and Assembly

1. Remove the brake bleeder screw.
2. Remove the dust boots, allow any brake fluid to drain out.

3. Remove the pistons, seals and inner spring.

4. Inspect the bore for scoring and corrosion. If bore is scored, replace cylinder. Do not hone the cylinder bores or polish the pistons. Replace the cylinder as an assembly if the bore is damaged. Black stains on the cylinder walls are caused by the piston cups and will not impair operation of the cylinder. Clean the cylinder with alcohol or brake fluid.

5. Lubricate the seals with brake fluid and install. Cup lips should always face inward. Install the spring assembly and seals.

6. Carefully install the pistons and dust boots.

7. Install the bleeder screw.

Caliper components—typical

Install dust boot on piston, then fold into place

Wheel Cylinder Service

The rear brakes are drum type with internal expanding shoes. The rear brakes are of the single anchor type, mounted to the same anchor and actuated by one wheel cylinder. The wheel cylinder has two pistons. Brake adjustments are automatic and are made during reverse brake applications.

Wheel cylinders may need reconditioning or replacement whenever the brake shoes are replaced or when required to correct a leak condition. Leaks which coat the boot and the cylinder with fluid, or result in a dropped reservoir fluid level, or dampen and stain the brake linings are dangerous. Such leaks can cause the brakes to grab or fail and should be immediately corrected. A leakage, not immediately

Anti-Lock Braking Systems

Despite advances in brake design over the years, even the best systems in use can still lock up during certain road conditions, such as wet road surfaces. When the brakes lock up, the driver can lose control of the vehicle, because a locked wheel cannot absorb any cornering or lateral forces, and steering is lost. It is impossible to brake to a maximum and at the same time steer the vehicle when the front wheels are locked. If the back wheels are locked the vehicle will become unstable and start to slide.

While many different ways have been tried over the years to solve this problem, mechanical sensors could not provide sufficient information about

Rear drum brakes—Comanche, Cherokee, Wrangler shown—typical

wheel rotation speed and mechanical control units could not operate the brakes fast enough to prevent brake lockup.

The growth of the electronics industry has allowed small computers (microprocessors) to be reduced in both size and cost. Coupled with fast reacting electronic sensors, anti-lock braking has become more reliable with widespread application.

Jeep's antilock brake system is available on 70 Series (Cherokee/Wagoneer Sport trucks) models with Select-Track four wheel drive. It is an electronically operated, power assisted, all wheel brake control system. The system is designed to retard wheel lockup during periods of high wheel slip when braking. Retarding wheel lockup is accomplished by modulating fluid pressures to the wheel brake units.

The 70 Series anti-lock system is a 3 channel design. The front wheel brakes are controlled individually and the rear wheel brakes in tandem.

System pressure is modulated according to wheel speed, degree of wheel slip and rate of deceleration. A sensor at each wheel converts wheel speed into electronic signals. The signals are transmitted to the brake system control unit for processing and determination of deceleration rate and wheel slip.

Basic system components include wheel sensors, fluid level and pressure switches, a pressure modulator, an accumulator, an electric booster pump, a master cylinder/power boost unit and an electronic control unit. Two instrument cluster indicator lights (one red, one yellow) are used to signal system condition and operating status.

The anti-lock electronic control system is separate from other electrical circuits in the vehicle. A specially programmed ECU is used for operational control.

The accumulator tank and the small accumulator on the booster pump both contain high pressure gas charges which assist in maintaining boost pressure. Do not puncture or attempt to disassemble either of these components at any time.

When servicing the anti-lock system, keep system components clean. Do not allow any dirt or foreign material to enter the system. Clean the reservoir cap and exterior thoroughly before removing the cap to add fluid. Dirt or foreign material in the system could result in poor brake system performance and possible component failure.

The manufacturer recommends Mopar brake fluid or equivalent meeting DOT 3 standards only. Never use reclaimed fluid or fluid from an open container that has been allowed to stand for any length of time.

CAUTION

The normal working pressure of the anti-lock boost system is 1650–2050 psi. System pressure must be pumped down before any pressure lines are loosened or disconnected. Failure to do so could result in personal injury. To reduce system pressure, turn the ignition key OFF. They apply the brakes 45–50 times (until pedal is firm) to reduce fluid pressure in the accumulator, booster, pump and lines. Wear safety goggles when disconnecting fluid lines.

MAJOR COMPONENTS

Master Cylinder/Power Booster Unit

The master cylinder and power booster pistons are located in a single, cast aluminum, cylinder body. A fluid reservoir is attached to the body with rubber seals.

The fluid reservoir is internally separated into 3 sections by bulkheads. A common fluid fill is used for the 3 sections.

The power booster is a demand type component. Power assist occurs only when the brakes are applied. Power assist is from high pressure brake fluid supplied by the electric motor driven booster pump. The pump is connected to the system accumulator. The accumulator is connected to the booster unit in the master cylinder.

Anti-lock master cylinder/power booster unit

Anti-lock booster pump and motor assembly

Pressure modulator channel—typical

Pump and Motor Assembly

The booster pump is powered by an electric motor. The motor and pump are combined in a common housing. The pump piston operates off an eccentric drive. An internal relief valve and a pressure switch control pump output. The housing contains a small accumulator which operates in tandem with the main accumulator.

The pump supplies fluid boost pressure for both standard and anti-lock brake operation. Pump operating pressure range is 1650–2050 psi. The pump motor is equipped with a thermal fuse which stops the pump if operating temperatures approach overheat range. The fuse does not reset once it is tripped.

Pressure Modulator

The pressure modulator is a hydro-

electric component. It provides three channels of pressure control to the front/rear brakes. One channel controls the rear wheel brakes in tandem. The two remaining channels control the front wheel brakes individually. Modulator inputs are both hydraulic and electronic.

The modulator contains a total of nine solenoid valves. Three valves are assigned to each control channel. The illustration shows one channel section of the modulator.

The 3 solenoid valves in each control channel have separate functions. The isolation solenoid valves isolate the master cylinder line to a caliper or wheel cylinder. The decay solenoid valves provide a controlled decrease (drop) in pressure to the wheel brakes in the anti-lock mode. The build solenoid valves provide controlled pressure build (increase) to the wheel brakes in the anti-lock mode.

Accumulator and Low Pressure Switch

The accumulator stores fluid under pressure for power brake and anti-lock operation. The low pressure switch monitors fluid pressure and is connected to the ECU.

If pressure falls below a minimum value of approximately 1050 psi, the

Accumulator and low pressure switch

Front wheel sensor and tone wheel

Rear wheel sensor and tone wheel

switch triggers the ECU which stops cycling the modulator solenoids. The yellow indicator light illuminates when the solenoids cease operation in the anti-lock mode.

The pressure switch is grounded through the vehicle body during normal operation but reverts to an open circuit if pressure drop occurs. An open circuit will trigger the instrument cluster indicator lights.

The accumulator is connected to the pump and power booster unit respectively.

Wheel Sensors

A sensor is used at each wheel. The sensors convert wheel speed into an electronic signal which is transmitted to the anti-lock ECU. A toothed-type tone wheel serves as the trigger mechanism for each sensor. The tone wheels are mounted at the outboard ends of the front and rear axle shafts.

Boost Pressure Differential Switch

The boost pressure differential switch is mounted in the pressure modulator. The switch checks the pressure differential between modulated boost pres-

Boost pressure differential and low fluid switch locations

sure and the master cylinder primary system pressure.

The switch is in circuit with the ECU and instrument panel indicator lights. The switch is open when pressure differential is normal. The switch will ground (through the vehicle body) if a pressure differential problem is detected. Once grounded, the switch signals the ECU to illuminate the indicator lights.

Fluid Level Switch

A fluid level switch is located in the master cylinder reservoir. The switch activates the red indicator light if the fluid level falls below the required level. The yellow light also comes on if the vehicle speed is above approximately 2.5 mph.

Electronic Control Unit

A separate electronic control unit (ECU) is used to monitor and control the entire anti-lock system. The ECU is attached to a bracket located under the rear seat. The power up voltage source for the ECU is through the ignition switch in the ON or RUN position.

The anti-lock ECU is separate from the other vehicle electronic systems. It contains a self-diagnostic program

Anti-lock electronic control unit

which triggers the indicator lights when a system fault is detected. Faults are stored in a diagnostic program memory. Faults remain in memory until cleared. However, if the battery is disconnected, stored faults are erased.

The ECU is also equipped with a mercury switch. The switch monitors the degree of vehicle deceleration to determine what type of surface the vehicle is on. The switch provides input to the ECU for improved operation in the 4WD mode on low traction (slippery) road surfaces.

NOTE: Proper mounting angle of the ECU is critical to correct and accurate operation of the mercury switch.

System Relays

There are 3 system relays. The yellow indicator light and modulator power relays are located on the driver side inner fender panel. The relay wires are in the engine compartment wire harness.

The pump/motor relay is part of the pump motor harness and is located at the passenger side of the engine compartment.

The modulator power relay is connected to the pressure modulator solenoids and the ECU. When the system is powered up, the ECU supplies the operating voltage (12 volts) to the solenoids through the relay.

The indicator light relay is connected to the modulator solenoid relay and the indicator light. The relay turns the yellow light on when the modulator power relay is off. The yellow light is turned off when the modulator power relay is energized.

The pump motor relay starts/stops the pump motor when signaled by the pump switch.

Anti-lock modulator/Indicator light relays and harness location

by the pump relay and by a pressure switch within the pump/motor assembly. The pump operates only when the ignition switch is in the ON or RUN position.

The pump does not run continuously. It cycles on/off with the pump pressure switch. The pump is capable of running with or without connection to the ECU. Pressurized fluid from the pump is transmitted to the accumulator and power booster unit.

The booster pump motor is equipped with thermal protection. If the motor approaches an overheat condition, a thermal fuse inside the pump will blow and shut off the motor. The fuse is not a reset-type and is not serviceable.

Sensor Inputs and Pressure Modulation

The wheel sensors and tone wheels supply wheel speed inputs to the ECU whenever the vehicle is in motion.

The ECU determines the degree of deceleration and wheel slip and provides optimum brake pressures for each control channel based on this data. The 70 Series (Cherokee/Wagoneer) anti-lock system provides 3 channel control. The front wheels are controlled individually. The rear wheels are controlled in tandem.

The ECU activates the pressure modulator solenoids which either build (increase), decay (decrease) or hold (maintain) fluid pressure as dictated by the ECU. The isolation solenoids isolate normal fluid pressure from the master cylinder to the rear wheels or to the left or right front wheel as needed. Wheel brake isolation occurs prior to build/decay solenoid operation.

Solenoid operation is not entirely constant in the anti-lock mode. Operation occurs in brief, rapid cycles front-to-rear and side-to-side. Rapid changes in input data will produce equally rapid changes in pressure modulation. The isolation, decay, and build functions are capable of function changes and cycle times measured in milliseconds.

SERVICE DIAGNOSIS

Wheel/Tire Size and Input Signals

Anti-lock system operation is dependent on signals from the wheel sensors. The vehicle wheels and tires must all be the same size and type in order to generate accurate signals. Variations in wheel/tire size will produce inaccurate input signals resulting in incorrect pressure modulation.

Operational Sound Levels

The booster pump and/or relay may produce a clicking sound as they cycle on and off. In addition, the booster pump and motor and the pressure modulator solenoids may generate a buzzing-type sound when operating. The sound is due to normal pump motor and system operation and is not indicative of a system fault. Under most conditions, the sound should not be audible.

Vehicle Response in Anti-lock Mode

During anti-lock braking, the pressure modulator solenoids cycle rapidly in response to ECU inputs.

As the solenoids in each channel isolate, build and decay pressure as needed, the driver may experience a slight pulsing sensation within the vehicle. A firmer brake pedal and some brake pedal pulsation may also be noted during anti-lock mode braking.

The pulsing sensation occurs as the individual brake units apply/release during anti-lock mode braking. Pulsing is a result of normal front-to-rear and side-to-side pressure modulation.

Indicator Light Operation

The red warning light and the yellow anti-lock indicator light both go on at start-up and go off when the engine is running. The one or two second illumination is part of a system self-test feature and indicates normal operation. System faults are indicated when one or both of the lights illuminate after initial start-up system check.

Driver Induced System Faults

Some driving or operational situations can induce faults in an anti-lock system that is actually operating correctly.

Induced faults are not true faults; a component malfunction as not actually occurred. Instead, they are a result of driver actions recognized by the diagnostic program as improper operation.

Improper parking brake use can induce faults in the self-diagnostic program. If a driver attempts to move the vehicle with the parking brakes applied, a system fault will register. Or, if the parking brake is applied while the vehicle is in motion, a system fault will also register. One or both indicator lights will illuminate in either situation. The red light illuminates for parking brake faults. The yellow light illuminates if a fault is sensed.

Faults can be induced in the system through excessive wheel spin. Wheel spin due to low traction surfaces or high speed acceleration can induce a

fault in a system that is operating normally. In addition, if system pressure is not restored after a repair, a fault will register when the vehicle is driven.

Pumping or riding the brake pedal may also induce a fault causing the indicator light to go on.

Steering Response

A modest amount of steering input is required during extremely high deceleration braking, or when braking on differing traction surfaces. An example of differing traction surfaces would be when the left side wheels are on ice, and the right side wheels are on dry pavement.

Loss of Sensor Input

Sensor malfunctions will most likely be due to loose connections, damaged sensor wires, or incorrect sensor-to-tone wheel air gap adjustment. Additional causes of sensor faults would be sensor and tone wheel misalignment or a damaged tone wheel.

System Diagnosis Procedures

Anti-lock system diagnosis involves three basic procedures. The first requires observation of indicator light display sequence. The second is a visual examination of system components for low fluid levels, leak points, or visible damage. The third involves using the manufacturer's diagnostic tester to check operation and locate a malfunctioning circuit.

The two indicator lights will illuminate separately, simultaneously, or with varying delays depending on the fault. The lights signal low fluid levels, pressure drops and other hydro-electrical faults. The service diagnosis charts for indicator light display can be used when a fault is detected.

COMPONENT SERVICEABILITY

The master cylinder/power booster unit, pressure modulator, accumulator, pump/motor and proportioning valve are not repairable components. If diagnosis indicates a malfunction has occurred, these components are to be replaced as a complete assembly.

The fluid level switch in the master cylinder and the boost pressure switch in the modulator are also not serviceable. The switches cannot be removed from their respective components.

The electrical harnesses, pump bracket, pump high pressure and supply hose, system relays and wheel sensors can be serviced individually.

The tone wheels are permanently attached to the axle shafts and are not

SERVICE DIAGNOSIS

SYSTEM FAULT	POSSIBLE CAUSE	INDICATOR LIGHT DISPLAY
LOW FLUID	SYSTEM LEAK. ACCUMULATOR CHARGE LOW OR LOST.	RED LIGHT ON. YELLOW LIGHT ON WITHIN 1/2 SECOND WHEN VEHICLE SPEED EXCEEDS 2.5 MPH.

Jeep Anti-lock diagnosis chart

18 BRAKES DOMESTIC

System components and location

replaceable. If a tone wheel becomes damaged, it will be necessary to replace the tone wheel and axle shaft as an assembly.

The wheel brake components such as calipers, brakeshoes, wheel cylinders, rotors and drums are all serviced the same as standard brake system components.

Wheel Sensors

The wheel sensors have a polyethylene spacer strip attached to the sensor contact face. When installing a sensor, be very sure this spacer strip actually touches the tone wheel. The strips are made in the exact thickness needed for correct sensor-to-tone wheel spacing (air gap). If the spacing (air gap) is too great, the sensors will not transmit accurate speed signals to the ECU.

If the spacer strip is missing from an original, or not provided on a replacement sensor, the correct sensor-to-tone wheel air gap will have to be established with a brass feeler gauge. A brass feeler gauge must be used to avoid disrupting sensor polarity.

If the sensor strip is missing from a reusable sensor, set the sensor-to-tone wheel air gap as follows:

Set front sensor air gap to 0.013–0.019 in.

Front sensor wire routing

Sensor contacts (spacer strip removed)

Set rear sensor air gap to 0.030–0.036 in.

Removal and Installation

FRONT WHEEL SENSOR

1. Raise and safely support vehicle and turn wheel outward for easier access to sensor.

2. Note the sensor wire routing for installation reference. Cut the tie straps holding wire to steering knuckle and brake line.

3. If sensor is covered with heavy

Sensor spacer strip

Adjusting sensor-to-wheel air gap

accumulations of dirt or mud, clean the sensor and surrounding area before proceeding. This is necessary to avoid possible damage when removing the sensor.

4. Remove the sensor attaching screw and remove the sensor from the steering knuckle.

5. Unseat the grommet holding the sensor wire in the wheel house panel.

6. In the engine compartment, disconnect the sensor wire connector at the anti-lock harness plug. Remove sensor and wire.

7. Before installing a new or reinstalling an original front wheel sensor, note the condition of the spacer strip. If the strip is securely attached and in good condition, a spacing (air gap) adjustment will not be needed. However, if the strip is loose or damaged, the correct air gap will have to be established with a brass feeler gauge.

8. To install a new sensor, route the wire through the wheelhouse grommet hole and connect the sensor to the harness plug. Seat the grommet.

9. Position the sensor on the steering knuckle and install the bolt finger-tight.

10. If the sensor strip was in good condition and securely attached, lightly press the sensor against the tone wheel and tighten the bolt to 11 ft. lbs.

11. If the sensor spacer strip is missing, loose or damaged and the sensor contacts are exposed, perform the following steps:

a. Remove the spacer strip if completely loose or torn. Wipe sensor contacts clean with a shop towel.

b. Set sensor-to-tone wheel air gap to 0.013–0.019 in. with a brass feeler gauge.

c. Tighten the sensor bolt to 11 ft. lbs. and recheck spacing.

12. Secure the sensor wire to the brake line and steering knuckle with new tie straps.

REAR WHEEL SENSOR REMOVAL

1. Raise and fold the rear seat forward for access to the rear sensor connectors. They are located near the ECU. Separate both sensor connections.

2. Push the sensor grommets and sensor wires through the floorpan.

3. Raise and safely support the vehicle and remove the wheel and brake drum.

4. Cut and remove the tie straps securing the sensor wires to the axle and rear brake hose.

5. Unseat the sensor backing plate grommet, remove the sensor attach bolt and remove the sensor by pulling the wire through the grommet hole in the backing plate.

6. Before installing a new or reinstalling an original rear wheel sensor, note the condition of the spacer strip. If the strip is securely attached and in good condition, a spacing (air gap) adjustment will not be needed. However, if the strip is loose or damaged, the correct air gap will have to be established with a brass feeler gauge.

7. If the sensor spacer strip is missing, loose or damaged and the sensor contacts are exposed, perform the following steps:

a. Remove the spacer strip if completely loose or torn. Wipe sensor contacts clean with a shop towel.

b. Set sensor-to-tone wheel air gap to 0.030–0.036 in. with a brass feeler gauge.

c. Tighten the sensor bolt to 11 ft. lbs. and recheck spacing.

8. Route the sensor wires to the rear seat area, feed the wires through the access holes and seat the grommets in the floorpan.

9. Secure the sensor wire with wire ties to the rear brake hose and axle. Make sure the wire is clear of rotating components.

10. Install the brake drum and wheel then lower vehicle.

11. Connect the sensors to the harness connects, reposition carpet and fold down rear seat.

BOOSTER PUMP AND MOTOR

CAUTION

The normal working pressure of the anti-lock boost system is 1650–2050 psi. System pressure must be pumped down before any pressure lines are loosened or disconnected. Failure to do so could result in personal injury. To reduce system pressure, turn the ignition key OFF. Then apply the brakes 45–50 times (until pedal is firm) to reduce fluid pressure in the accumulator, booster, pump and lines. Wear safety goggles when disconnecting fluid lines.

1. Turn the ignition switch to the OFF position and apply the brakes

Rear sensor connectors

Rear sensor wire routing and attachment

Rear sensor installation

(pump pedal) 45–50 times (until pedal is firm on initial apply) to reduce system fluid pressure.

NOTE: When the reserve pressure is depleted, the reservoir fluid level will rise above the MAX fill mark but will not overflow unless the reservoir was overfilled to begin with.

2. Disconnect the battery negative cable.

3. Remove the coolant pressure bottle retaining strap and move the reservoir aside. It is not necessary to disconnect the bottle hoses, just move the bottle aside for working clearance.

4. Remove the bolts holding the two-piece mounting bracket to the dash and inner fender panels. Rotate the bracket and pump/motor assembly to one side for access to the wires and

hoses. Disconnect the pump motor harness from the engine harness.

5. Slowly loosen the pump pressure line at the pump and allow any residual fluid pressure to bleed off, then disconnect the line from the pump.

5. Put a drain container under the pump return line, loosen the return line hose clamp and remove the line from the pump. Discard any drained fluid.

6. Remove the pump/motor and bracket as an assembly.

7. Remove the relay from the bracket and separate the components.

8. When installing, position the pump/motor assembly on the bracket and install the assembly attaching screws along with the relay.

9. Connect the pressure and return lines to the pump as well as the motor harness.

10. Position the mounting bracket on the dash panel and install the attaching bolts and screws. Check the line routing, making sure the lines are not kinked or touching the engine.

11. Clean the master cylinder exterior and cap. Fill the reservoir to the top of the V-shaped MAX indicator mark with DOT 3 rated brake fluid.

Note: Do not overfill the reservoir. Overfilling will cause overflow and could damage the reservoir. Add fluid to the V-shaped MAX indicator only.

12. Connect the battery and turn the ignition to **ON** to start the pump running. While the pump is running, listen for an rpm drop which indicates the pump is pressurizing. If the pump rpm does not drop after 20 seconds, immediately turn the ignition **OFF** and check the pump hydraulic connections.

NOTE: Do not allow the pump to run if it does not pressurize. If the pump rpm does not drop after 20 seconds run time, turn the ignition OFF immediately to avoid pump damage.

13. Add fluid to master cylinder reservoir if necessary.

MASTER CYLINDER

The master cylinder, modulator and accumulator are serviced as an assembly only. Do not attempt to disassemble or repair these components.

CAUTION

CAUTION: The normal working pressure of the anti-lock boost system is 1650–2050 psi. System pressure must be pumped down before any pressure lines are loosened or disconnected. Failure to do so could result in personal injury. To reduce system pressure, turn the ignition key **OFF**. Then apply

Pump motor harness and relay

Pump pressure and supply line connections

the brakes 45–50 times (until pedal is firm) to reduce fluid pressure in the accumulator, booster, pump and lines. Wear safety goggles when disconnecting fluid lines.

1. Pump system pressure down by turning the ignition **OFF** and applying the brake pedal 45–50 times until the pedal becomes firm.

2. Disconnect the battery. Remove the windshield washer fluid reservoir attaching screws, disconnect the hoses and wires and remove the reservoir.

3. Remove the air cleaner assembly, disconnect the ECU harness wire connectors at the pressure modulator and disconnect the wires at the proportioning valve differential switch.

4. Disconnect the high pressure line at the accumulator block. Cap the line to keep out dirt.

5. Disconnect the supply line at the reservoir. Cap the line to keep out dirt. Discard any fluid that drains from the line.

6. Disconnect the low pressure switch wires, and the wires at the modulator boost pressure and fluid level switches.

7. Disconnect the front brakelines at the outboard side of the pressure modulator.

8. In the passenger compartment, remove the instrument panel lower trim cover for access to the brake pedal. Disconnect the brakelight switch wires, remove the master cylinder pushrod bolt and disconnect the pushrod from the pedal. Discard the push-

rod bolt nuts as they are not reusable.

9. Remove the master cylinder mounting bracket stud nuts.

10. In the engine compartment, pull the brake hydraulic components and mounting bracket forward until the bracket studs are clear of the dash. Lift the assembly up and out of the engine compartment.

11. At installation, place pad on the mounting bracket and position assembled bracket and brake components on dash panel. Be sure bracket studs are seated in dash panel holes.

12. Position master cylinder/modulator/accumulator assembly on dash panel. Tighten stud nuts to 27 ft. lbs.

13. Connect the harness wires to the modulator, low pressure switch, differential switch and the low fluid and boost pressure switches.

14. In the passenger compartment, install the nuts of the mounting studs and torque to 31 ft. lbs.

15. Align the brake pedal, brakelight switch, master cylinder push rod and install the pushrod bolt.

NOTE: The pushrod bolt must be installed correctly to avoid interference with the dash bracket. The bolt must be installed with the bolt head at the left side of the pedal.

16. Install new nuts on the push rod bolt. Tighten the inner lock nut to 25 ft. lbs. and the outer jam nut to only 75 in. lbs. Connect the brake light switch wires and install the lower trim panel.

17. In the engine compartment, connect the brake lines to the proportioning valve and connect the pressure and return lines to the accumulator.

18. Install the air cleaner assembly, connect the hoses and wires to the washer reservoir and install the reservoir to the fender panel.

19. Clean the master cylinder exterior and cap. Fill the reservoir to the top of the V-shaped MAX indicator mark with DOT 3 rated brake fluid.

20. Connect the battery and turn the ignition to **ON** to start the pump running. While the pump is running, listen for an rpm drop which indicates the pump is pressurizing. If the pump rpm does not drop after 20 seconds, immediately turn the ignition **OFF** and check the pump hydraulic connections.

NOTE: Do not allow the pump to run if it does not pressurize. If the pump rpm does not drop after 20 seconds run time, turn the ignition OFF immediately to avoid pump damage.

21. Add fluid to master cylinder reservoir if necessary.

22. Bleed the brake system.

DIAGNOSTIC CONNECTOR			
PHASE	DATA OUT	ENABLE	YELLOW LT.
PRODUCTION	D2-5	D1-4	D2-14

Anti-lock ECU wiring diagram

ECU harness and fluid connections

ECU mounting bracket

Fluid line connections

Removing/Installing master cylinder, modulator and accumulator assembly

ECU

1. Make sure the ignition is **OFF**, then fold the rear seat cushion forward for access to the ECU.
2. Remove the screws attaching the ECU mounting bracket to the floorpan, remove the screws attaching the ECU to the mounting bracket, unplug the ECU and remove.
3. At installation, connect the harness of the replacement ECU.
4. Install the replacement ECU on the bracket and install the bracket to the floorpan.
5. Fold down rear seat.

SYSTEM BLEEDING

1. Fill reservoir to V-shaped maximum fill mark.
2. Bleed the brakes in the following sequence: right rear, left rear, right front, left front.
3. Attach a bleed hose to the caliper or wheel cylinder being bled, immerse the end of the bleed hose in a glass container partially filled with brake fluid.
4. Turn the ignition **ON** to cycle the pump.
5. Have a helper apply brake pedal to pressurize the system. Open the bleed screw $\frac{1}{2}$ turn. Close the bleed screw when the fluid entering the glass container is free of bubbles.
6. Check the reservoir fluid level and add fluid to the **MAX** fill mark.
7. Repeat bleeding operations at remaining wheels.

NOTE: Do not allow the master cylinder reservoir to run dry while bleeding the brakes. Running dry will allow air to re-enter the system making a second bleeding operation necessary. More importantly, if air re-enters the system, it could damage the pump seriously enough to require replacement.

Typical brake system schematic

brake parts contains asbestos fibers which can become airborne if dust is generated during brake servicing. Continuously breathing this dust can cause serious bodily harm. A dampened cloth or a spray bottle with water should be used to remove brake dust prior to work. Equipment is also commercially available for safe brake servicing.

The hydraulic system controls the braking operation and consists of a master cylinder, hydraulic lines and hoses, control valves and calipers and/or wheel cylinders. When the brake pedal is depressed, the master cylinder forces brake fluid regulated by the proportioning valve to the calipers and/or cylinders, via lines and hoses. Rubber seals throughout the system contain the fluid and prevent leakage.

Return springs in the master cylinder help the brake pedal return to the original unapplied position. Check valves (in most cases) regulate the return flow of the fluid to the master cylinder. Other valves, such as the metering valve, proportioning valve, or combination valve, regulate the flow of fluid to the caliper/wheel cylinder, to achieve even and efficient braking.

Dual Braking Systems

The dual system uses a tandem master cylinder, consisting of 2 separate pistons in a single cylinder bore. Dual brake lines split the calipers and/or wheel cylinders into 2 groups, each actuated by a separate master cylinder piston. In event of failure of 1 of the systems, the other should provide enough braking power to safely stop the vehicle. The dual system usually includes a red warning light on the instrument panel which is activated by a pressure differential valve. The valve is sensitive to any loss of hydraulic pressure that might result from a braking failure on either side of the system.

Light trucks are equipped with either a front/rear wheel split or a diagonally split system. On front/rear sys-

IMPORT BRAKE SYSTEM SERVICE

Hydraulic System Basics

CAUTION

When servicing brake parts, do not create dust by grinding the linings or by blowing them clean with compressed air. Many

tems, the front wheels are connected to one circuit while the rear wheels are connected to the other circuit. Diagonally split systems have diagonally opposite wheels connected to each circuit.

Brake Fluid

Approved DOT3 heavy duty type brake fluid retains the correct consistency throughout the widest range of temperature variation, will not affect rubber cups or seals, helps protect the metal parts of the brake system against failure and has a high boiling point to assure long trouble free brake operation when properly maintained.

Never use brake fluid from a container that has been used for any other liquid. Mineral oil, alcohol, antifreeze, or cleaning solvents, even in very small quantities, will contaminate brake fluid. Contaminated brake fluid will cause rubber parts within the hydraulic system to swell or deteriorate. Always return the cap to the fluid container after using the brake fluid. This will prevent the fluid from absorbing moisture from the surrounding air, which will lower its boiling point. Do not use brake fluid that has been sitting in an unopened container for an extending amount of time.

Hydraulic Line Repair

Steel tubing is used for the hydraulic lines between any 2 parts that do not move independant of one another, like the master cylinder and the front brake tube connector, or along the axle tubes between the brake tee and the rear brake cylinders. Brake hoses provide a flexible connection between the tube and a part that moves independantly, like the hose that connects the brake tube to the front brake calipers or the tube that runs along the body of the vehicle conneted by hose down to the axle.

BRAKE TUBING

If a section of the brake tube becomes damaged, the entire section should be replaced with tubing of the same type, size, shape, and length. Copper tubing should not be used in the hydraulic system. When bending brake tubing to fit the frame or axle contours, be careful not to kink or crack the tube.

All brake tubing should be double flared to provide good leak proof connections. Always clean the inside of a new brake tube with clean isopropyl alcohol before installing.

BRAKE HOSE

All flexible brake hoses should be carefully inspected often. They should be replaced if they show any signs of softening, cracking, swelling or other damage.

When installing a new brake hose, make sure it is not twisted and is positioned to avoid contact with other vehicle components under any suspension condition.

Hydraulic Control Valves

PRESSURE DIFFERENTIAL VALVE

The valve activates a panel warning lamp in event of pressure loss failure. As pressure fails in one split system, the other system's normal pressure causes a piston in the switch to compress a spring and move until an electrical circuit is completed lighting the dash lamp. Normally, the spring balanced piston automatically recenters when the brake pedal is released, thus flashing the warning lamp only during brake application and will re-center automatically after repairs are successfully completed and the system is properly bled.

METERING VALVE

Often used on vehicles equipped with front disc and rear drum brakes, the metering valve improves braking balance during light brake applications by preventing application of the front disc brakes until the pressure to the rear brakes overcomes the tension of the rear brake shoe return springs. Thus, when the front brake pads contact the rotor the rear brakes shoes move outward to contact the brake drum at approximately the same time.

The metering valve should be inspected whenever the brakes are serviced. A slight amount of moisture inside the boot does not indicate a defective valve, however a great deal of fluid indicates a faulty valve and replacement is recommended. Make sure to install the brake lines in the correct ports when installing a new valve, crossed lines will cause the hydraulic system to malfunction.

PROPORTIONING VALVE

The proportioning valve is used to transmit full inport pressure to the rear brakes up to a certain point (the split point). Beyond the split point, it reduces the amount of pressure to the

rear brakes according to a certain ratio, which is built into the valve. On light pedal applications, equal braking pressure is transmitted to the front and rear brakes. During heavier brake applications, however, the pessure delivered to the rear brakes is lower than that at the front brakes to prevent rear wheel lockup and skidding.

Whenever the brakes are serviced, the valve should be inspected. To check valve operation, install hydraulic gauges ahead of and behind the valve and determine that it has an operative transition point above which rear brake pressure is proportioned. If the valve is leaking replacement is required.

COMBINATION VALVE

A valve combining two or three functions (metering, proportioning, and/or brake warning) may be used. The combination valve is usually mounted under the hood close to the master cylinder, where the brake lines can be easily routed to the front and rear wheels. The combination valve is a non-serviceable unit, and if found to be malfunctioning, must be replaced as a unit.

Disc Brakes

CALIPERS

Caliper disc brakes can be divided into 3 types: dual piston floating caliper, single piston floating caliper and single piston sliding caliper. On the floating caliper types, the inner pad is hydraulically pushed into contact with the disc, while the reaction force generated is used to pull the outer pad into contact with the other side of the disc, made possible by allowing the caliper to move slightly along the axle's center line. Two pistons may be used to accomodate more severe braking requirements on heavier vehicles. All disc brake systems are self-adjusting and have no provision for annual adjustment.

With the sliding caliper type, the caliper assembly slides along the smooth and lubricated surface of a key or stopper (nomenclature varies between manufacturers) which is held stationary by cotter pins or retaining bolts. The caliper is held against the key or stopper with 1 or 2 support springs.

One of the recent developments in brake equipment materials includes the use of aluminum calipers for the purpose of saving weight. A vast array of anti-rattle springs, clips and anti-squeal pads and shims are used by manufacturers to prevent the pads from making any undesirable noises.

Excessive runout of parallelism

Wobble pump action resulting from a warped rotor

In addition, most brake pads are comprised of semi-metallic materials for improved stopping power. Unfortunately, these pads often produce an annoying brake squeal as they are used, but the squeal itself should not reduce the stopping ability of the pads. If the pad kit includes plates or shims, use them when servicing the disc brakes. Aftermarket spreads and sprays are also available to quiet noisy pads. It is always a good idea to replace calipers in pairs.

ROTORS

Rotors provide the surface upon which the brake pads stop the vehicle. It is important to inspect the rotor carefully. Manufacturers differ some on permissible runout (warpage) of the rotor, but excessive runout can usually be felt as a pulsation at the brake pedal regardless of the specification. A wobble pump effect is created when the rotor is not perfectly flat and the pad hits a high spot forcing fluid back into the master cylinder. This alternating pressure causes a pulsation which is felt at the pedal when the brakes are applied. An excessive amount of runout can cause the pads to be out of adjustment because they cannot hold themselves against the rotor at all times. It is always a good idea to replace rotors in pairs.

To check the actual runout of the ro-

tor, first tighten the spindle nut to remove all endplay. Fasten a dial indicator on the suspension on a convenient location so the pin contacts the rotor surface about 1 in. from its outer edge. Set the dial at 0 and check the runout while turning the rotor 1 full revolution. If the rotor is warped beyond limits, the rotor should be replaced. Rotors that are not warped beyond the specification can be resurfaced, as long as the final thickness is not below the minimum thickness requirement of the rotor.

Lateral Runout: The wobbly movement of the rotor from side to side as it rotates. Excessive lateral runout causes the rotor faces to knock back the pads and can cause brake chatter, shudder or vibration.

Parallelism (lack of): This refers to the amount of variation in the thickness of the rotor. Excessive variation of parallelism can cause a pulsating pedal, front end vibrations or grabbing conditions; a condition comparable to an out-of-round brake drum. Check parallelism with a micrometer. Measure the thickness of the rotor at 8 or more equally spaced locations on the rotor, equally distant from the outer edge, preferably at the mid-point of the braking surface. A lack of parallelism results if the difference between the highest and lowest measurement is beyond the parallelism specification.

Surface or Micro-inch finish, flatness and smoothness: These terms all refer to the degree of perfection of the flat surfaces on each side of the rotor. Visually inspecting the rotor, the machined surface should have a fine ground polish with a swirling pattern to reduce brake squeal.

DISC BRAKE PADS

The brake pads are the tools that the vehicle uses to stop, so they should be inspected very carefully. Pads should be replaced only in sets (both sides of

the same axle) if any of the pads is damaged, cracked, burnt, or separated from the plate that it is glued or riveted to. Replace the pads if any of their lining is worn down to $\frac{1}{16}$ in. thickness. If the lining is allowed to wear beyond this point, severe and costly damage to the rotor may result. Note that individual state inspection guidelines take precedence over these general recommendations.

Floating caliper type disc brake pads may wear at an angle; the measurement should always be taken at the narrowest end of the taper. Tapered lining should be replaced if the amount of tapering exceeds $\frac{1}{8}$ in. from end to end and the cause of the taper should be investigated and repaired, if possible.

To prevent potentially costly paint damage, remove some brake fluid from the master fluid reservoir and install the reservoir cover before servicing the pads. When installing new pads, the caliper piston is forced back into its bore and fluid is pushed back into the master cylinder. The fluid could spill and remove paint from any painted surface that it comes in contact with.

When the caliper is removed from its mounting adaptor, do not allow it to dangle by the brake hose. This can damage the hose and create a dangerous situation. Always rest the caliper on a suspension member of suspension from the frame with a wire or rope.

Drum Brakes

WHEEL CYLINDERS

The wheel cylinder performs in response to the master cylinder. It receives fluid from the hydraulic tube through its inlet port. As the pressure increases, the wheel cylinder cups and pistons are forced apart. As a result, the hydraulic pressure is converted into mechanical force acting on the brake shoes. The variation in wheel cylinder size (diameter) is one of the factors controlling the distribution of braking force in a vehicle. Bleeder screws are provided to remove air or vapor trapped in the system.

Wheel cylinders may need reconditioning or replacement whenever the brake shoes are replaced or when required to correct a leak condition. On many designs, the wheel cylinders can be disassembled without removing them from the backing plate. On some designs, however, the cylinder is mounted in an indentation in the backing plate or a cylinder piston stop is welded to the backing plate. When servicing brakes of this type, the cylinder must be removed from the backing plate before being disassembled.

Leaks which coat the boot and the cylinder with fluid, or result in a dropped reservoir fluid level, or dampen and stain the brake linings are dangerous. Such leaks can cause the brakes to grab or fail and should be immediately corrected. A leakage, not immediately apparent, can be detected by pulling back the cylinder boot. A small amount of fluid seepage dampening the interior of the boot is normal, however a dripping boot is not. Unless other conditions causing a brake to pull, grab, or drag becomes obvious, the wheel cylinder is a suspect and should be included in general reconditioning. It is always a good idea to service wheel cylinders in pairs.

Cylinder binding may be caused by rust, deposits, grime, or swollen cups due to fluid contamination, or by a cup wedged into an excessive piston clearance. If the clearance between the pistons and the bore wall exceeds allowable values, a condition called heel drag may exist. It can result in rapid cup wear and can cause the pistons to retract very slowly when the brakes are released. A ring of a hard, crystal like substance is sometimes noticed in the cylinder bore where the piston stops after the brakes are released.

BRAKE DRUMS

The condition of the brake drum surface is equally as important as the surface of the lining. All drum braking surfaces should be clean, smooth, free of hark spots; heat damage, scoring and foreign material embedded in the braking surface. The drum should not be out-of-round, bell mouthed or barrel shaped. Drums should be checked with a drum micrometer before resurfacing to see if it within over-size limits. If the drum is within safe limits, it should be machined to true the drum surface and to remove any contamination in the surface from previous linings and road matter. Too much metal removed from the drum is unsafe and may result in brake fade due to the thin drum not being able to absorb the heat generated, vibration from ensuing drum distortion and generally unsafe conditions.

Brake drum runout should not exceed 0.005 in. Drums machined to more than 0.060 in. oversize are unsafe and should be replaced. It is always good practice to replace drums on both wheels at the same time to ensure even braking.

If the drums are in good condition, smooth up any slight scoring by sanding with coarse sand paper, then polishing with emery cloth. If deep scores or grooves are present, machine the drums to restore them to good operating condition.

DRUM BRAKE SHOES

The brake shoes should also be inspected very carefully. Shoes should be replaced only in sets (both sides of the same axle) if any of the shoes are bent, damaged, cracked, burnt, or separated from the plate that it is glued or riveted to. Replace the shoes if any of their lining is worn down to $\frac{1}{16}$ in. thickness. If the lining is allowed to wear beyond this point, severe and costly damage to the drum may result. Note that individual state inspection guidelines take precedence over these general recommendation.

Rear brakes with weak return springs may create a bell-mouthed condition which causes the shoes to wear at an angle; if so the measurement should always be taken at the narrowest end of the taper. Tapered linings should be replaced if the amount of tapering is excessive and the cause of the taper should be investigated and repaired, if possible.

Disassemble and assemble one side at a time to prevent improper assembly. This will also provide a model that can be referred if the installation doesn't look right. Always complete the brake shoe adjustment with the wheels installed and adjust the parking brake cable last.

STAR AND SCREW ADJUSTER

Star and screw self-adjusters are used on most late-model vehicles. This system requires manual adjustment only when the shoes have been replaced, when the star wheel has been disturbed or when the star wheel is not operating properly. As the star wheel is turned, it expands or contracts the shoes accordingly.

In most cases, the brakes can be initially adjusted by removing the drum, measuring the internal diameter of the drum and setting the shoes to slightly less than that measurement. Normally, the brakes will self-adjust when the vehicle is backed up and the brakes are firmly applied.

CHRYSLER IMPORTS/ MITSUBISHI

NOTE: When cleaning brake system components, use only brake fluid or denatured isopropyl alcohol. Never use a mineral-

based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir retainer screw, if equipped and remove the reservoir and seals or remove the reservoir unions and seals.
2. Push the primary piston in and remove the stopper bolt and gasket.
3. Hold the pistons in and remove the snapping.

NOTE: Do not disassemble either piston assembly as the individual parts are not serviceable.

4. Let the primary piston spring out and remove the primary piston assembly.
5. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side outlet port if it does not come out easily.
6. Remove the brake line connector block and washers.

To assemble:

7. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid.
8. Install both assemblies to the master cylinder.
9. Push the pistons in and install a new snapping.
10. Hold the pistons in and install the stopper bolt with a new gasket.
11. Install the brake fluid reservoir or unions with new seals. Install the reservoir retaining screw, if equipped.
12. Install the connector block with new washers.

Brake Booster Service

The brake boosters installed on these vehicles are not serviceable. If the unit is defective, replace the entire assembly.

Chrysler/Mitsubishi master cylinder

Chrysler/Mitsubishi caliper

Chrysler/Mitsubishi wheel cylinder

Caliper Service

Disassembly and Assembly

1. Remove the bleeder screw.
2. Drain the brake fluid from the caliper.
3. Remove the dust boot ring and the dust boot.
4. Position a shop rag opposite the

top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seal from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the dust boot mounting groove and install the boot. Install the retaining ring.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

Wheel Cylinder Service

Disassembly and Assembly

1. Remove the bleeder screw, if equipped.

2. Remove both rubber boots.

3. Remove the piston assemblies, each consisting of the piston and cup.

4. Remove the piston cups from the pistons, being careful not to scratch the piston.

5. Remove the return spring.

6. Hone the cylinder bore if it is not damaged, to provide a smooth sealing surface. Wash and dry the bore after honing.

To assemble:

7. Lubricate the cylinder bore with brake fluid.

8. Lubricate the new piston cups and install them to the pistons, with their lips facing upward. Install the assemblies to the cylinder.

9. Apply lubricant to the boot mounting groove and install the boot.

10. Apply rust penetrant to the bleeder screw threads and install to the wheel cylinder. Tighten it until it is just snug against its seat.

ISUZU

NOTE: When cleaning brake system components, use only brake fluid or denatured isopropyl alcohol. Never use a mineral-based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within

the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir retainer screw.
2. Remove the reservoir and seals.
3. Remove the dust seal from the end of the master cylinder.
4. Push the primary piston in and remove the stopper bolt and gasket.
5. Hold the pistons in and remove the snapping.

NOTE: Do not disassemble either piston assembly as the individual parts are not serviceable.

6. Let the primary piston spring out and remove the primary piston assembly and end washer, if equipped.

7. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side outlet port if it does not come out easily.

To assemble:

8. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid. Install both assemblies to the master cylinder.

9. Push the pistons in and install a new snapping.

10. Hold the pistons in and install the stopper bolt with a new gasket.

11. Install the brake fluid reservoir with new seals. Install the reservoir retaining screw.

Disassembly and Assembly

EXCEPT 1988-90 PICK-UP AND AMIGO WITH 2.6L ENGINE AND 1988-90 TROOPER II

1. Remove the clevis yoke and locknut from the actuator rod. Remove the low vacuum switch (diesel only).

2. Pry out the servo retainer and seal from the front of the shell.

3. Remove the rubber boot.

CAUTION

The rear shell is spring loaded. Loosen it slowly and carefully or personal injury may result.

4. Matchmark the front and rear shells. Using wrench J-9504-01 and holder J-34250, separate the 2 shells slowly. Remove the servo spring.

5. Remove the entire diaphragm plate assembly.

6. Pry out the servo retainer, bearing and valve body seal from the rear shell.

7. Using a knife, cut the vacuum servo diaphragm and remove. Make sure not to damage the valve body when cutting.

8. Remove the servo retainer from the valve body.

9. Remove the vacuum filter and silencers from the valve body.

10. Push in the actuating rod and remove the rod stopper key. Remove the actuating rod assembly.

11. Remove the reaction disc, valve body, diaphragm plate and pushrod assembly.

To assemble:

12. Install the new actuating rod assembly to the valve body. Push the rod in and install the rod stopper key.

13. Install the new vacuum silencers and filter.

14. Install the new retainer to the rear shell.

15. Install the diaphragm plate and carefully attach the new vacuum servo diaphragm to the valve body.

16. Apply silicone grease to the new reaction disc and install to the valve body. Install the pushrod and spring.

17. Apply silicone grease to the rear shell seal and install.

18. Mount the holding tool J-34350 in a vise and mount the front shell on the tool. Assemble the entire diaphragm plate assembly to the rear shell. Install the bearing and new retainer.

19. To assemble the unit, connect a vacuum source to the vacuum intake pipe on the front shell. Using the matchmarks as guides, apply vacuum and assemble the unit using tool J-9504-01. Make sure the bent area of the of the diaphragm does not drop against the front and rear shell engaging areas.

20. Rotate the rear shell clockwise until the notch on the rear shell is fully against the stopper. Tighten until the matchmarks are perfectly aligned.

21. Install the new rubber boot, locknut and clevis yoke.

22. Apply silicone grease to the last seal and install to the front shell. Install the remaining retainer over the seal.

23. Install the low vacuum switch, if equipped.

TANDEM VACUUM SERVO

Disassembly and Assembly

1988-90 PICK-UP AND AMIGO WITH 2.6L ENGINE

1. Remove the clevis yoke and locknut from the actuator rod.

2. Remove the rubber boot.

3. Install holding tool J-34350 to the mounting studs and clamp in a vise. Matchmark the front and rear shells. Install wrench J-9504-01 to the rear shell studs.

CAUTION

The rear shell is spring loaded. Loosen it slowly and carefully or personal injury may result.

4. Connect a vacuum source to the vacuum intake pipe on the front shell. Rotate the lever counterclockwise slightly (about $\frac{1}{20}$ turn). The front shell caulking tab must be aligned with the V-groove on the outside of the rear shell. Exhaust the vacuum and pry the rear shell from the front shell.

5. Remove the retainer, bearing and seal from the rear shell.

6. Remove the retainer and remove the filter and silencers from the actuating rod.

7. Remove the retainer and remove the rear diaphragm from the valve body. Remove the rear diaphragm plate.

8. Remove the C-ring from the valve body. Push the actuating rod down, remove the stopper key and remove the actuating rod from the valve body.

9. Remove the center plate and remove the retainer, seal and bearing from the plate.

10. Remove the retainer and remove the front diaphragm from the valve body.

11. Raise the catch that holds the valve body and front diaphragm plate together. Turn the plate and remove it from the valve body.

12. Remove the pushrod, reaction disc, retainer and spring from the front shell.

13. Remove the retainer and seal from the front shell.

To assemble:

14. Apply silicone grease to the seal and install to the front shell and install the retainer over the seal. Lubricate the diaphragm sliding surfaces on the inside of the shell with the same grease.

15. Lubricate the pushrod stem and install to the hub reaction disc.

16. Lubricate and install a new O-ring to the valve body. Set the diaphragm plate on the valve body and rotate it to install. Install the new front diaphragm and retainer.

★ REPAIR KIT

Isuzu tandem vacuum servo—1988-90 Trooper II

17. Lubricate and install the bearing, seal and retainer to the center plate.

18. Use installer J-38595 to install the center plate assembly to the valve body.

19. Align the arrow mark on the rear diaphragm plate with the mark on the valve body and install the plate with a tilting motion. Install a new retainer to the front diaphragm.

20. Lubricate and install the actuating rod to the valve body and install the C-ring. Push the actuating rod and install the stopper key.

21. Install the first filter, the silencer then the second filter to the valve body and install the new retainer.

22. Lubricate and install the seal, bearing and retainer to the rear shell.

23. Mount the holding tool J-34350 in a vise and mount the front shell on the tool. Assemble the entire center plate assembly to the rear shell.

24. To assemble the unit, connect a vacuum source to the vacuum intake pipe on the front shell. Using the matchmarks as guides, apply vacuum and assemble the unit using tool J-9504-01. Make sure the bent area of the of the diaphragm does not drop against the front and rear shell engaging areas.

25. Rotate the rear shell clockwise until the notch on the rear shell is fully against the stopper. Tighten until the matchmarks are perfectly aligned.

26. Install the new rubber boot, locknut and clevis yoke.

27. Adjust the pushrod length to 0.7 in. (18.2mm) from the base of the front shell.

1988-90 TROOPER/TROOPER II

1. Remove the clevis yoke and locknut from the actuator rod.

2. Pry out the servo retainer and seal from the front of the shell.

CAUTION

The rear shell is spring loaded. Loosen it slowly and carefully or personal injury may result.

3. Matchmark the front and rear shells. Using wrench J-9504-01 and holder J-34250 (holes elongated to fit), separate the 2 shells slowly. Remove the servo spring.

4. Remove the rubber boot.

5. Remove the retainer, bearing and seal from the rear shell.

6. To disassemble the diaphragm assembly, remove the large nut with a 1½ in. wrench.

7. Remove the front diaphragm plate, front diaphragm and center plate.

8. Remove the retainer, center plate seal and bearing from the center plate.

9. Remove the pushrod and carefully pry the key out of the valve body. Remove the key retainer.

10. Rotate the reaction disc hub 90 degrees and release it from the center body. Remove the reaction disc and O-ring.

11. Remove the center body and dia-

phragm from the rear diaphragm plate.

12. Remove the valve body assembly. Remove the retainer and remove the actuating rod.

13. Remove the retainer and remove the filters and silencer from the rod.

To assemble:

14. Install the valve body to the rear diaphragm plate. Install the retainer with the cutouts to the valve body lugs and install the actuating rod.

15. Install the new rear diaphragm.

16. Install the center body and new lubricated O-ring. Set the retainer against the outer pawl of the reaction and rotate the reaction disc 90 degrees to install.

17. Install the key retainer, push in the actuating rod and install the stopper key.

18. Install the new filter, silencer, second filter and retainer.

19. Install the reaction disc (with the stepped side inward) and pushrod.

20. Lubricate and install the bearing, center plate seal and retainer to the center plate.

21. Install the front diaphragm to its plate and install 1½ in. nut.

22. Lubricate and install the seal, bearing and retainer to the rear shell. Install the new rubber boot.

23. Mount the holding tool J-34350 in a vise and mount the front shell on the tool. Assemble the entire diaphragm assembly, spring and the rear shell.

24. To assemble the unit, connect a

vacuum source to the vacuum intake pipe on the front shell. Using the matchmarks as guides, apply vacuum and assemble the unit using tool J-9504-01. Make sure the bent area of the of the diaphragm does not drop against the front and rear shell engaging areas.

25. Rotate the rear shell clockwise until the notch on the rear shell is fully against the stopper. Tighten until the matchmarks are perfectly aligned.

26. Install locknut and clevis yoke.

27. Apply silicone grease to the last seal and install to the front shell. Install the remaining retainer over the seal.

Caliper Service

Disassembly and Assembly

FRONT CALIPER

1. Remove the bleeder screw.
2. Drain the brake fluid from the caliper.
3. Remove the dust boot ring and the dust boot.
4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seal from inside the bore.
- To assemble:**
6. Blow out all fluid passages with low pressure compressed air.
 7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pit-

ted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the dust boot mounting groove and install the boot. Install the retaining ring.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

REAR CALIPER

1. Remove the sleeve and its dust boot. Remove the mounting pin dust boot.
2. Remove the bleeder screw.
3. Drain the brake fluid from the caliper. Remove the dust boot ring and the dust boot.
4. To remove the piston, unscrew it using tool J-37617. Remove the piston seal.
5. Remove the snapping at the bottom of the caliper bore. Pull out the pad adjusting spindle along with the retainer, spring, spring plate and stopper. Remove the O-ring from the spindle.

6. Remove the parking brake link from the bottom of the caliper bore.
7. Remove the parking brake lever, spring and dust boot.
8. Remove the return spring and dust boot.

To assemble:

9. Apply brake system compatible grease to the parking brake link and install.
10. Lubricate and install the new O-ring to the pad adjusting spindle. Attach the stopper, spring plate, spring and retainer to the spindle. Turn the

embossed side of the stopper to the outer side and align the cutaways of the stopper and retainer.

11. Insert the spindle assembly into the caliper bore fitting the stopper to the groove at the bottom of the bore. Install the snapping and position it so that the open area between ends aligns with the bleeder.

12. Lubricate the piston seal and install to the groove in the caliper. Install the piston and using tool J-37617, turn the piston clockwise until it bottoms. Align the piston cutouts with the inspection window in the caliper body. If this is not done, the brake pads will wear unevenly.

13. Apply lubricant to the dust boot mounting groove and install the boot. Install the retaining ring.

14. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

15. Install the new parking brake lever dust boot, spring and lever. Torque the retaining bolt to 35 ft. lbs. (47 Nm).

Wheel Cylinder Service

Disassembly and Assembly

1. Remove the bleeder screw.
2. Remove both rubber boots.
3. Remove the pistons from the cylinder.
4. Remove the piston cups.
5. Remove the return spring.
6. Hone the cylinder bore if it is not damaged, to provide a smooth sealing surface. Wash and dry the bore after honing.

To assemble:

7. Lubricate the cylinder bore with brake fluid. Install the return spring.
8. Lubricate the new piston cups and install them to the cylinder. Lubricate and install the pistons.
9. Apply lubricant to the boot mounting groove and install the boot.
10. Apply rust penetrant to the bleeder screw threads and install to the wheel cylinder. Tighten it until it is just snug against its seat.

Isuzu front caliper

MAZDA

NOTE: When cleaning brake system components, use only brake fluid or denatured isopropyl alcohol. Never use a mineral-based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within

Isuzu rear caliper

the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir retainer screw.
2. Remove the reservoir and seals.
3. Remove the dust seal from the end of the master cylinder.
4. Push the primary piston in and remove the stopper bolt and gasket.
5. Hold the pistons in and remove the snapping.

6. Let the primary piston spring out and remove the primary piston assembly and end washer, if equipped.
7. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side outlet port if it does not come out easily.

To assemble:

8. Assemble the secondary piston assembly, if it was disassembled. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid. Install both assemblies to the master cylinder.

9. Push the pistons in and install a new snapping.
10. Hold the pistons in and install the stopper bolt with a new gasket.
11. Install the brake fluid reservoir with new seals. Install the reservoir retaining screw.

Brake Booster Service

The brake booster on the MPV is not serviceable. If the unit is defective, replace the entire assembly.

Mazda master cylinder

SINGLE DIAPHRAGM

Disassembly and Assembly

2WD PICK-UP

1. Remove the clevis yoke and locknut from the actuator rod.
2. Pry out the servo retainer and seal from the front of the shell.
3. Remove the rubber boot.

CAUTION

The rear shell is spring loaded. Loosen it slowly and carefully or personal injury may result.

Mazda single diaphragm booster

4. Matchmark the front and rear shells. Using the special tools, separate the 2 shells slowly. Remove the servo spring.

5. Remove the entire diaphragm and plate assembly.

6. Pry out the retainer, bearing and seal from the rear shell.

7. Using a knife, cut the vacuum diaphragm and remove. Make sure not to damage the power piston assembly when cutting.

8. Remove the retainer from the power piston.

9. Remove the vacuum filter and silencers from the power piston.

10. Push in the valve rod and remove the retainer key. Remove the valve rod assembly.

11. Remove the reaction disc, power piston, diaphragm plate and pushrod assembly.

To assemble:

12. Install the new valve rod assembly to the power piston. Push the rod in and install the retainer key.

13. Install the new vacuum silencers and filter.

14. Install the new retainer to the rear shell.

15. Install the diaphragm plate and

Mazda double diaphragm booster

carefully attach the new vacuum diaphragm to the power piston.

16. Apply silicone grease to the new reaction disc and install to the power piston. Install the pushrod and spring.

17. Apply silicone grease to the rear shell seal and install.

18. Mount the front shell in a vise. Assemble the entire diaphragm plate assembly to the rear shell. Install the bearing and new retainer.

19. To assemble the unit, connect a vacuum source to the vacuum intake pipe on the front shell. Using the matchmarks as guides, apply vacuum and assemble the unit using the special tool. Make sure the bent area of the of the diaphragm does not drop against the front and rear shell engaging areas.

20. Rotate the rear shell clockwise until the notch on the rear shell is fully against the stopper. Tighten until the matchmarks are perfectly aligned.

21. Install the new rubber boot, locknut and clevis yoke.

22. Apply silicone grease to the last seal and install to the front shell. Install the remaining retainer over the seal.

DOUBLE DIAPHRAGM

Disassembly and Assembly

4WD PICK-UP

1. Remove the clevis yoke and locknut from the actuator rod.

2. Pry out the servo retainer and seal from the front of the shell.

CAUTION

The rear shell is spring loaded. Loosen it slowly and carefully or personal injury may result.

3. Matchmark the front and rear shells. Using the special tools, separate the shells. Remove the rubber boot.

4. Clamp holding tool 49-U043-002 in a vise and mount the rear shell assembly to the tool. Uncrimp the reaction disc hub. Remove the locknut using wrench 49-U043-001.

5. Remove the retainer, bearing and seal from the rear shell.

6. Remove the front diaphragm plate, front diaphragm and center plate.

7. Remove the retainer, center plate seal and bearing from the center plate.

8. Remove the pushrod and carefully pry the key out of the valve body.

9. Remove the key retainer.

10. Rotate the reaction disc hub 90 degrees and release it from the center body. Remove the reaction disc and O-ring.

11. Remove the center body and dia-

phragm from the rear diaphragm plate.

12. Remove the valve body assembly. Remove the retainer and remove the actuating rod.

13. Remove the retainer and remove the filters and silencer from the rod.

To assemble:

14. Install the valve body to the rear diaphragm plate. Install the retainer with the cutouts to the valve body lugs and install the actuating rod.

15. Install the new rear diaphragm.

16. Install the center body and new lubricated O-ring. Set the retainer against the outer pawl of the reaction and rotate the reaction disc 90 degrees to install.

17. Install the key retainer, push in the actuating rod and install the stopper key.

18. Install the new filter, silencer, second filter and retainer.

19. Install the reaction disc (with the stepped side inward) and pushrod.

20. Lubricate and install the bearing, center plate seal and retainer to the center plate.

21. Install the front diaphragm to its plate and install locknut using the special wrench. Crimp the reaction disc hub in the 2 notched grooves of the locknut.

22. Lubricate and install the seal, bearing and retainer to the rear shell. Install the new rubber boot.

23. Align the notches of the rear shell and center plate. Make sure the bent area of the of the diaphragm does not drop against the front and rear shell engaging areas.

24. Push down and rotate the rear shell clockwise until the notch on the rear shell is fully against the stopper. Tighten until the matchmarks are perfectly aligned.

25. Install locknut and clevis yoke.

26. Apply silicone grease to the last seal and install to the front shell. Install the remaining retainer over the seal.

Caliper Service

Disassembly and Assembly

1. Remove the bleeder screw.

2. Drain the brake fluid from the caliper.

3. Remove the dust boot.

4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seal from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the dust boot mounting groove and install the boot.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

Wheel Cylinder Service

Disassembly and Assembly

1. On the left side, remove the bleeder screw and check ball.

Mazda caliper

3. Piston rubber cups
4. Piston cups
5. Spring
6. Rubber cap
7. Bleeder
8. Steel ball

2. Remove both dust boots.
3. Remove the pistons.
4. Remove the piston cups.
5. Remove the return spring.
6. Hone the cylinder bore if it is not damaged, to provide a smooth sealing surface. Wash and dry the bore after honing.

To assemble:

7. Lubricate the cylinder bore with brake fluid. Install the return spring.
8. Lubricate the new piston cups and install them to the cylinder. Lubricate and install the pistons.
9. Apply lubricant to the boot mounting groove and install the boot.
10. Apply rust penetrant to the bleeder screw threads and install it with the check ball to the wheel cylinder. Tighten until just snug.

Nissan master cylinder—Pick-Up and Pathfinder

Nissan master cylinder—Van and Axxess

2. Push the primary piston in and remove the stopper cap.
3. Let the primary piston spring slowly out and remove the primary piston assembly.
4. Inspect the stopper cap carefully. If either claw is damaged in any way, replace it.
5. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side outlet port if it does not come out easily. Disassemble the secondary piston

on Pick-Up and Pathfinder only. The secondary pistons on Axxess and Van are not serviceable.

To assemble:

6. Assemble the secondary piston assembly, if it was disassembled. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid. Install both assemblies to the master cylinder.

7. Push the pistons in and install the stopper cap.

8. Install the fluid reservoir and seals, if equipped.

Brake Booster Service

The brake boosters installed on these vehicles are not serviceable. If the unit is defective, replace the entire assembly.

Caliper Service

SINGLE PISTON TYPE

Disassembly and Assembly

1. Remove the bleeder screw.
2. Drain the brake fluid from the caliper.
3. Remove the dust seal ring (rear caliper only) and the dust seal.
4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

Nissan single piston front caliper

Nissan rear caliper

NISSAN

NOTE: When cleaning brake system components, use only brake fluid or denatured isopropyl alcohol. Never use a mineral-based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir and seals or hoses.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seal from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the dust seal mounting groove and install the seal. Install the retaining ring, if equipped.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

DOUBLE PISTON TYPE

Disassembly and Assembly

1. Remove the bleeder screw.
2. Drain the brake fluid from the caliper.
3. Remove the dust covers.
4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the pistons out of their bores. If both pistons do not come out, install the extracted piston back into its bore just enough to seal; then hold it place with a suitable spacer. Blow out the remaining piston.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seals from inside the bore.

Nissan double piston caliper

Nissan wheel cylinder

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seals and install in the grooves.

9. Lubricate the pistons and install them to the bores until they bottom. If either piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the dust seal mounting grooves and install the seals.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

Wheel Cylinder Service

Disassembly and Assembly

1. Remove the bleeder screw.
2. Remove both dust covers.
3. Remove the pistons.
4. Remove the piston cups.
5. Remove the return spring.
6. Hone the cylinder bore if it is not damaged, to provide a smooth sealing surface. Wash and dry the bore after honing.

To assemble:

7. Lubricate the cylinder bore with brake fluid. Install the return spring.

8. Lubricate the new piston cups and install them to the cylinder. Lubricate and install the pistons.

9. Apply lubricant to the dust cover mounting groove and install the cover.

10. Apply rust penetrant to the bleeder screw threads and install to the wheel cylinder. Tighten it until it is just snug against its seat.

SUZUKI/GEO

NOTE: When cleaning brake system components, use only

brake fluid or denatured isopropyl alcohol. Never use a mineral-based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir screw of roll pin and remove the reservoir. Remove the seals.

2. Push the primary piston in and remove the snapping.

3. Let the primary piston spring slowly out and remove piston stopper, cups and the primary piston assembly.

4. Remove the secondary piston stopper bolt.

5. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side outlet port if it does not come out easily. Disassemble the secondary piston.

To assemble:

6. Assemble the secondary piston assembly. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid. Install both assemblies to the master cylinder.

7. Install the cups and stoppers. Install the snapping.

8. Push the pistons in and install the stopper bolt.

9. Install the fluid reservoir and seals.

Brake Booster Service

SINGLE DIAPHRAGM TYPE

SAMURAI

1. Remove the piston rod from the booster.

2. Remove the pushrod clevis and locknut.

3. Mount the booster on the holding tool set 09950-88210. Do not tighten the 2 outer nuts to more than 30 inch lbs. or the booster may become deformed.

4. Turn the special tool bolt clock-

Suzuki master cylinder—Samarai

Suzuki/Geo master cylinder—Sidekick and Tracker

wise until the projection and depression in the bodies match. Matchmark the bodies at that location.

5. Remove the booster from the tool and separate the bodies.

CAUTION

The rear body is spring loaded. Loosen it slowly and carefully or personal injury may result.

6. Remove the boot, air cleaner elements and air cleaner separator from the rear body.

7. Turn the booster piston counterclockwise and remove from the rear body.

8. Push the air valve down and remove the stopper key. Remove the air valve assembly from the booster piston.

9. Remove the diaphragm from the pressure plate.

10. Remove the reaction disc from the booster piston.

11. Remove the seal from the from the rear body.

To assemble:

12. Lubricate and install a new seal to the rear body.

13. Lubricate and install the booster air valve to the booster piston.

14. Compress the valve and install the stopper key.

15. Install the new diaphragm to the pressure plate. Make sure the diaphragm is seated securely in its groove in the pressure plate.

16. Lubricate the face and install the reaction disc to the booster piston.

17. Install the booster piston to the rear body by turning it clockwise into place.

18. Install the new air cleaner separator and elements to the air valve rod.

19. Install the boot to the rear body.

20. Place the front body on the special tool and place the return spring on it large end up.

21. Place the assembled rear body on the return spring and compress. Turn the special bolt counterclockwise until the projection and depression line up.

22. Install the piston rod into the booster piston.

23. Install the locknut and clevis.

SIDEKICK AND TRACKER

1. Remove the pushrod clevis.

2. Remove the locknut.

3. Mount the booster on the holding tool set 09950-88210. Do not tighten the 2 outer nuts to more than 30 inch lbs. or the booster may become deformed.

4. Turn the special tool bolt clockwise until the projection and depression in the bodies match. Matchmark the bodies at that location.

5. Remove the booster from the tool and separate the bodies.

CAUTION

The rear body is spring loaded. Loosen it slowly and carefully or personal injury may result.

6. Remove the piston rod, boot, air cleaner elements and air cleaner separator from the rear body.

7. Remove the valve stopper key cushion.

8. Push the air valve down and remove the stopper key. Remove the air valve assembly from the booster piston.

9. Remove the diaphragm circular ring from the booster piston. Remove the diaphragm from the pressure plate.

10. Remove the reaction disc from the booster piston.

11. Remove the seal from the from the rear body.

To assemble:

12. Lubricate and install a new seal to the rear body.

1. Vacuum check valve

Suzuki/Geo single diaphragm booster—Sidekick and Tracker

13. Install the retainer to the diaphragm. Install the diaphragm to the booster piston and install the new diaphragm circular ring.

14. Lubricate and install the booster air valve to the booster piston. Compress the valve and install the stopper key. Install the cushion to the notch in the stopper.

15. Install the booster piston to the rear body.

16. Install the new air cleaner separator and elements to the air valve rod.

17. Install the boot to the rear body.

18. Lubricate the face and install the reaction disc to the booster piston.

19. Place the front body on the special tool and place the return spring,

rod retainer and piston rod on it.

20. Place the assembled rear body on the return spring and compress. Turn the special bolt counterclockwise until the projection and depression line up.

21. Install the piston rod into the booster piston.

22. Install the locknut and clevis.

Caliper Service

Disassembly and Assembly

1. Remove the bleeder screw.

2. Drain the brake fluid from the caliper.

3. Remove the cylinder boot.

4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seal from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the cylinder boot mounting groove and install.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

Wheel Cylinder Service

Disassembly and Assembly

1. Remove the bleeder screw, if equipped.

2. Remove both rubber boots.

3. Remove the piston assemblies, each consisting of the piston and cup.

4. Remove the piston cups from the pistons, being careful not to scratch the piston.

5. Remove the return spring.

6. Hone the cylinder bore if it is not damaged, to provide a smooth sealing

outlet port if it does not come out easily.

To assemble:

6. Assemble the pistons, if they were disassembled.

7. Coat the master cylinder bore and secondary and primary piston seals liberally with brake fluid.

8. Install both assemblies to the master cylinder.

9. Push the pistons in and install a new snapping.

10. Hold the pistons in and install the stopper bolt with a new gasket. Install a new boot.

11. Install the brake fluid reservoir or unions with new seals. Install the reservoir retaining screw, if equipped.

surface. Wash and dry the bore after honing.

To assemble:

7. Lubricate the cylinder bore with brake fluid.

8. Lubricate the new piston cups and install them to the pistons, with their lips facing upward. Install the assemblies to the cylinder.

9. Apply lubricant to the boot mounting groove and install the boot.

10. Apply rust penetrant to the bleeder screw threads and install to the wheel cylinder. Tighten until it is just snug against its seat.

Do not hone any aluminum bores. There is a hard anodized coating on the aluminum which will be removed if honed. This will allow the aluminum to wear quickly and will damage the component.

Master Cylinder Service

Disassembly and Assembly

1. Remove the brake fluid reservoir retainer screw, if equipped and remove the reservoir and seals or remove the reservoir unions and seals.

2. Remove the boot. Push the primary piston in and remove the stopper bolt and gasket.

3. Hold the pistons in and remove the snapping.

NOTE: Do not disassemble either piston assembly on the Pick-Up and 4Runner. The individual parts are not serviceable.

4. Let the primary piston spring out and remove the primary piston assembly.

5. Remove the secondary piston assembly. This may be accomplished by carefully blowing low pressure compressed air through the secondary side

Brake Booster Service

The brake boosters installed on these vehicles are not serviceable. If the unit is defective, replace the entire assembly.

Caliper Service

SINGLE PISTON TYPE

Disassembly and Assembly

1. Remove the bleeder screw.

2. Drain the brake fluid from the caliper.

3. Remove the boot.

4. Position a shop rag opposite the top of the piston. Apply low pressure compressed air to the fluid inlet and carefully blow the piston out of the bore.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

NOTE: When cleaning brake system components, use only brake fluid or denatured isopropyl alcohol. Never use a mineral-based solvent such as gasoline or paint thinner; these fluids will leave a residue that may swell and deteriorate rubber parts within the system. All alcohol must be removed from the system when the work is done because alcohol mixed with brake fluid lowers its boiling point.

5. Remove the piston seal from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

7. Slight corrosion or rust can be removed with commutator paper or crocus cloth. Replace pistons that are pitted, scored, peeling or otherwise damaged.

8. Lubricate the caliper bore with brake fluid. Lubricate the seal and install it in the groove.

9. Lubricate the piston and install it to the bore until it bottoms. If the piston will not go in by hand, it is probably cocked. Remove it and reinstall.

10. Apply lubricant to the boot mounting groove and install the boot.

11. Apply rust penetrant to the bleeder screw threads and install to the caliper. Tighten it until it is just snug against its seat.

FOUR PISTON TYPE

Disassembly and Assembly

1. Remove the bleeder screw.
2. Drain the brake fluid from the caliper.
3. Remove the boot set rings and boots.
4. Position a suitable block of wood across the caliper and use an old brake pad to keep 1 pair of pistons in their bores. Apply low pressure compressed air to the fluid inlet and carefully blow the pistons out of their bores. Reinsert the piston just enough to seal and reverse the old brake pad in order to blow out the remaining pistons.

CAUTION

Do not put fingers where the piston will land when it is blown out of the caliper. The force of the piston can crush fingers and cause personal injury.

5. Remove the piston seals from inside the bore.

To assemble:

6. Blow out all fluid passages with low pressure compressed air.

8. Lubricate the new piston cups and install them to the cylinder. Lubricate and install the pistons.

9. Apply lubricant to the dust cover mounting groove and install the cover.

10. Apply rust penetrant to the bleeder screw threads and install to the wheel cylinder. Tighten it until it is just snug against its seat.

Emission Controls

19

EMISSION CONTROLS

Emission control devices are designed to eliminate the chemical compounds that escape from the engine crankcase, from the exhaust and from evaporation of fuel out of the tank and carburetor. With the growing use of on-board computers, it has become possible for car manufacturers to meet strict Federal emission standards by using electronic engine controls to monitor operating conditions and adjust engine calibrations for the best possible performance and economy with minimum emissions.

Engine calibration has a big effect on emissions out the tailpipe. The calibration consists of spark timing, fuel mixture, choke setting, idle speed and spark plug gap. Calibrations are not a service problem as long as the engine is adjusted to the factory specifications, which are found on a sticker in the engine compartment. Engines must be adjusted to these factory specifications or emissions will be high. Additionally, emission control systems have become such an integral part of the overall engine design that best engine performance is dependent on best emission control system performance. This is especially true for computer controlled systems.

NOTE: Any attempt to disconnect or bypass any OEM emission device is a violation of federal law.

The latest emission control systems use electronic instead of vacuum devices and are much more sensitive to

malfunctions in any component. Following is a description of each group of controls and how they work to reduce emissions. Due to the complex nature of modern electronic engine control systems, comprehensive diagnosis and testing procedures fall outside the confines of this repair manual. For complete information on diagnosis, testing and repair procedures concerning all modern engine and emission control systems, please refer to *Chilton's Guide To Electronic Engine Controls*.

Emission Service Indicators

RESET PROCEDURES

Indicator lights or flags will periodically appear on or near instrument cluster to alert the driver that various emission control components need to be serviced or replaced. Most of the reminder lights are triggered at preset mileages programmed into either mechanical or electronic counter or odometer switches. The mechanical counter switches are normally operated by the speedometer cable, while the electronic counter switches are pulsed by a speed sensor usually located in the speedometer assembly. After servicing the indicated emission system (EGR valve, Oxygen sensor, etc.), the service indicator device will have to be reset to eliminate the light or flag. Follow the appropriate procedure outlined below for each year and model listed.

American Motors

The reset switch is located under the

hood on the left side of the firewall, between the upper and lower speedometer cables. There is a rest screw on the unit that must be rotated one-quarter turn to the detent position.

Chrysler Corporation

1980 MODELS

Chrysler models use either electronic or mechanical service counters. The electronic switch is located under the instrument panel somewhere near the lower left instrument cluster. It is usually covered with a green plastic case.

To reset the mechanical switch, remove it from the mounting bracket and then remove the plastic case. Insert a small screwdriver or rod into the hole in the switch body to close the contacts and turn off the indicator light. To reset the mechanical switch, first locate the unit between the upper and lower speedometer cables. Turn the screw on the upper side of the switch to reset.

General Motors

1980 CADILLAC

To reset the switch, remove the lower steering column cover and locate the reset cable at the lower left side of the speedometer cluster. Pull the cable lightly to reset the switch, then replace the column cover. Do not pull hard on the cable or damage to the cable and switch will occur.

1980 AND LATER MODELS

An emission indicator flag will appear in the odometer window when service is necessary on some 1980 and later GM models. The flags are marked SENSOR, EMISSION, or

19 EMISSION CONTROLS

FLAG WINDOW IN SPEEDOMETER FACE

RESETTING FLAG WITH DOWNWARD MOVEMENT

FLAG IN RESET POSITION

Resetting Emissions flag on 1980 GM models—typical

CATALYST, depending on the device that is schedule for regular maintenance. To reset the flag, first remove the instrument panel trim plate and instrument cluster cover lens. There are reset notches on the driver's side of the indicator flag.

Insert a long, pointed probe diagonally into the detents on the upper left side and rotate the flag downward until an alignment mark becomes visible in the left side of the odometer window. Once the flag has been lowered, replace the cluster lens and trim plate.

CRANKCASE CONTROLS

PCV System

Ventilation of a crankcase is necessary because of the compression blow-by past and piston rings. This blow-by is mostly unburned gasoline. If allowed to stay in the crankcase, it di-

lutes the oil and increases engine wear. The PCV system uses engine vacuum to draw out the crankcase fumes. The crankcase or the rocker arm cover is connected by a hose to engine vacuum at the intake manifold or carburetor. When the engine is running, the crankcase fumes are drawn into the engine and burned in the combustion chamber. Fresh air

PCV valve operation

enters the crankcase through the oil filler cap on the open system. When the oil filler cap is connected to the air cleaner, it is known as a closed system.

At wide open throttle, there is little vacuum in the engine, so the PCV system doesn't pull any fumes out of the crankcase. Because the hose connection from the crankcase to the intake manifold acts like a vacuum leak, there has to be some kind of control to limit the air flow. The PCV valve is the control. It can be an actual valve, with an internal plunger, or a simple orifice without any moving parts. In the plunger types, a spring moves the plunger against engine vacuum, allowing less flow at high vacuum and more flow at low vacuum. In the event of a backfire, the plunger moves to close the PCV valve and prevent a possible crankcase explosion.

Fresh air enters the air cleaner and goes through a hose to the crankcase or rocker cover. The fumes exit the crankcase and enter the intake manifold, either through a hose or some other type of connection, usually with a PCV valve controlling the flow. Most systems use some kind of PCV filter, usually mounted at the end of the hose in the air cleaner. The filter keeps dust from entering the crankcase and also prevents oil fumes from ruining the air cleaner element.

Typical open crankcase ventilation system

GM diesel V8 engines are equipped with one of two different crankcase ventilation systems. The first system uses a crankcase vacuum regulator valve to meter the flow of crankcase gases back into the engine. The regulator limits crankcase vacuum as the gases are drawn from the valve covers through the regulator, and into the air crossover. This system is used on 1981 and later non-California models. Other models use a crankcase flow control valve to meter the blow-by gases back into the engine. On these models, a ventilation hose runs from each valve cover and connects the flow control valve, which is screwed into the back of the air crossover.

TESTING PCV SYSTEMS

NOTE: Do not attempt to test the crankcase controls on GM V8 diesels. Instead, clean the valve cover filter assemblies and vent pipes and check rubber fittings every 15,000 miles, and replace or clean the breather cap assembly and ventilation regulator valve (if equipped) every 30,000 miles.

Checking crankcase vacuum is the most effective way to test any PCV system. If there is a vacuum in the crankcase, then the major part of the system has to be working. Inspect the system to find out where the fresh air enters the engine. This is usually through a hose attached to the air cleaner, but it may be through the oil filler cap on some models. If the fresh air entry is separate from the oil filler cap, simply remove the cap.

On all models, use a piece of paper or a PCV tester to measure the crankcase vacuum at the oil filler cap, with the cap removed and the engine idling in Park or Neutral. It may take a few seconds for the vacuum to build up enough to suck the piece of paper against the oil filler hole. If the vacuum does not build up, check to be sure you have plugged the fresh air entry. An alternate method on some cars is to use the piece of paper or PCV tester on the end of the fresh air entry hose. When you do it that way, the oil filler cap must be the solid type and you must leave it in place.

If there is no crankcase vacuum, pull the PCV valve from the crankcase and hold your finger over the end of it. You should feel full manifold vacuum with the engine idling. If not, the valve is plugged or there is an obstruction in a hose or passageway. On some designs the valve may be screwed into its mounting, with a hose leading to the rocker cover or crankcase. If the valve has good suc-

tion, but there is no crankcase vacuum, check the hose to be sure it is open. PCV valves that are restricted or plugged must be replaced, unless they are the type that will come apart for cleaning. Lack of crankcase vacuum can also be caused by vacuum leaks at rocker cover, oil pan, or other engine gaskets. Usually, tightening the bolts will stop the leak.

In some extreme cases, usually on high mileage engines, the PCV system is in good shape, but the blow-by past the rings is so much that the system can't handle it, and the engine will blow smoke out the oil filler hole. Switching to a PCV valve with a higher flow may temporarily correct the problem. But the only good solution is to overhaul the engine. If the motor oil is contaminated with gasoline, the PCV system will pick up the unburned vapors, add them to the intake mixture and cause the engine to run excessively rich. After checking crankcase vacuum, always check the condition of the fresh air filter and hose, to be sure they are clean and not clogged.

NOTE: The PCV system operation is not computer controlled, but if inoperative it will directly affect the operation of any computerized emission system. If poor performance is a problem, check the PCV system first.

running, a hose to the intake manifold or carburetor base allows engine vacuum to pull fresh air through the canister, drawing the vapors into the engine where they are burned. Fresh air enters the canister through a filter, which keeps the charcoal clean.

When the engine is running, air must enter the tank to replace the fuel that is used up and prevent a vacuum. On all makes of canister storage models, air enters the tank through the filter in the canister, but air can also enter the tank through the pressure-vacuum tank cap.

All evaporation control systems use some sort of vapor separator at the fuel tank to prevent liquid fuel from traveling along the vent line to the canister. The early models had very elaborate separators mounted separately from the tank, but now they are simpler and usually attached to the top of the tank. The only periodic servicing required on evaporation controls is replacement of the canister filter on those models on which it is replaceable.

NOTE: If the vent lines become blocked, it is possible for some evaporation control systems to pull liquid fuel from the tank into the charcoal canister. If any charcoal canister is found to be fuel-soaked it should be replaced and all hoses checked for obstructions.

FUEL EVAPORATION CONTROLS

Charcoal Canister Vapor System

Evaporation controls are made up of hoses which allow the tank and carburetor vapors to go to a canister filled with charcoal. When the engine is

EXHAUST CONTROLS

Thermostatic Air Cleaner (TAC)

Fresh air supplied to the air cleaner comes either from the normal snorkle, or from a tube connected to an exhaust manifold stove. A door in the snorkle regulates the source of incoming air so that a warm engine always

Vapor storage canister operation—typical

Vacuum controlled thermostatic air cleaner.

A typical heated air cleaner system, with the hot air pipe connected to the left exhaust manifold

takes in warm air, approximately 100°F. The snorkel door may be controlled in any number of ways, but most are vacuum operated. The vacuum operated designs use a thermostatic bimetal switch inside the air cleaner that bleeds off vacuum as the engine warms up and regulates the position of the air door.

Vacuum operated air doors are all designed so that the air cleaner takes in cold air when there is no vacuum. This means that an air door in the hot air position will switch to the cold position at wide open throttle because of the loss of manifold vacuum. The sudden switching of the door from hot to cold may cause a stumble or misfire in the engine, so some designs include a modulator valve mounted on the side of the air cleaner to block the vacuum and hold the door in the hot air position. A small thermostat inside the modulator opens it when the underhood temperatures reach normal. Other designs used a delay valve that allows the air door to move to the

cold position slowly, to prevent stumble.

TESTING TAC OPERATION

To test the vacuum type of heated air cleaner, inspect the air door with the engine off. It should be in the cold air position. Start the engine. If the engine is cold, the air door should move to the hot air position. As the engine warms up, the air door should move to a mid position, depending on the outside air temperature.

If the outside air is extremely cold, the air door may stay in the hot air position indefinitely. On a warm day, after the engine warms up, the air door should move to the cold air position. If it doesn't, the temperature sensor inside the air cleaner might be faulty, or the air door itself might be hanging up. Check the air door (a small mirror can be helpful here) by using a hand vacuum pump, or by running a hose from manifold vacuum to the vacuum

motor. Connect and disconnect the hose to see if the air door moves freely. If the air door is free, check out the hoses for leaks or blockage. If the hoses are okay, the trouble must be in the temperature sensor, and it should be replaced.

Both General Motors and Ford use a modulator in the air cleaner vacuum line on some engines. The modulator mounts on the side of the air cleaner and has two hose connections, one to the air cleaner temperature sensor, and the other to the vacuum motor. Below 50–80°F, the modulator is a one-way check valve, which allows vacuum to move the air door to the hot air position, but traps the vacuum so the door will not jump back to the cold air position during acceleration. This prevents a stumble.

After the module warms up the check valve unseats so that the vacuum can pass freely in either direction, and the air door then operates normally. The connections from the modulator are important. The connection in the center (usually the larger diameter) goes to the vacuum motor, and the connection on the edge goes to the vacuum source, which is the temperature sensor.

To test the modulator on a cold engine, apply enough vacuum to the edge port to move the air door to the hot position. Then remove the hose from the port, and the air door should stay in the hot position. Make the same test when the engine is warmed up, and the air door should move to the cold position when you pull off the hose.

Exhaust Gas Recirculation (EGR)

Gasoline Engines

NOx (oxides of nitrogen) is a tailpipe emission caused by the oxidation of nitrogen in the combustion chamber. When the peak combustion temperatures go over 2500°F, NOx is formed in excessive amounts. To keep the combustion temperatures down, exhaust gas is recirculated by allowing intake manifold vacuum to draw exhaust gas into the intake manifold. The lower combustion temperatures also help control spark knock (ping).

An EGR valve is used to control the flow of exhaust gas into the intake manifold. All EGR valves look similar and are operated by vacuum. When the vacuum is off, the valve is closed. Several different types of controls are used to turn the vacuum to the EGR valve on and off. Most of them have to do with engine temperature, as de-

Venturi vacuum exhaust gas recirculation

scribed later. On computerized control systems, EGR operation is regulated by the electronic control unit.

NOTE: All EGR systems are designed to cut off exhaust recirculation when the engine is cold, at idle, or under hard acceleration. If the EGR valve is stuck open, the engine won't idle.

TESTING EGR SYSTEM

CAUTION

The EGR valve gets hot during normal operation. Take normal precautions to avoid accidental burns.

Testing of EGR systems should verify that when the engine is at normal operating temperature the EGR valve is closed at idle, open above idle, and that the exhaust gas is actually recirculating. If the EGR valve sticks open at idle, the engine will run very rough, or may not even start. If this happens the valve should be removed and cleaned or replaced. To check for valve operating above idle, check with a mirror to see if the diaphragm or stem moves when the engine is at fast idle in Park or Neutral. If the diaphragm does not move when the throttle is opened, there is either a problem with vacuum, or the valve is stuck closed. With a vacuum gauge hooked up to the EGR port, you should see vacuum on the gauge when the throttle is opened. EGR valves should not leak when tested with a hand vacuum pump. If they do they must be replaced.

NOTE: The EGR valve should open when about 3–5 in. Hg. is ap-

plied with a hand vacuum pump. Back pressure operated EGR valves cannot be vacuum tested.

To find out if the exhaust gas is actually recirculating, use a hand vacuum pump to open the EGR valve with the engine idling. If the engine runs rough or dies, the exhaust gas is recir-

culating. If the engine does not run rough, make a second test of 2500 rpm. Opening the EGR valve at that rpm should cause a change in engine speed. If it does, the exhaust gas is recirculating. To make the 2500 rpm test, remove and plug the hose from the EGR port. Attach the suction hose to the EGR valve before running the engine at 2500 rpm. Simply pulling off the EGR hose at 2500 rpm is not a valid test, because the extra air entering the engine through the hose could cause a speed change by itself.

If the exhaust is not recirculating, it means that a passageway or the valve itself is clogged up. The only way to fix it is to clean out the clogging as best you can, replace the clogged part, or replace the EGR valve. Many EGR valves have a back pressure sensor built into the valve. This sensor is a pressure operated bleed that disables the EGR valve and keeps it closed when there is no exhaust pressure. This type of valve cannot be tested with a hand vacuum pump with the engine off because the bleed is open. The only practical way to test these new valves is by substitution of a known good valve. If a valve is not available, the suspect valve can be removed, and the mounting holes temporarily taped shut. If this cor-

Most cars use an EGR system with a valve and a ported vacuum signal, as shown here. Some cars use the venturi vacuum with a separate amplifier to operate the valve.

rects the problem, then a new valve should be installed.

Diesel EGR Systems

GM V6 and V8 Engines

GM has equipped its V8 and V6 diesel engines with EGR systems. The diesel EGR systems work in the same basic manner as gasoline engine EGR systems: exhaust gases are introduced into the combustion chambers to reduce combustion temperatures, and thus lower the formation of nitrogen oxides (NOx). There are two systems used on the V8 diesels. One is used on the B (large body) type station wagons, and one system is used on all other cars.

On the B-body station wagon EGR

GM V6 diesel EGR valve

GM V6 diesel Exhaust Pressure Regulator Valve (EPR)

Typical catalytic converter installation

system, vacuum from the vacuum pump is modulated by the Vacuum Regulator Valve (VRV) mounted on the injection pump. Vacuum is highest at idle and decreases to zero at wide open throttle. The EGR valve is therefore fully open at idle and closed at wide open throttle. A Response Vacuum Reducer Valve is used between the VRV and the EGR valve to allow the EGR valve to change position quickly as throttle position is changed.

On all other V8 diesel engines, the EGR system is the same as used on the B-body wagon, except a solenoid is added to the system that shuts off vacuum to the EGR valve when the Torque Converter Clutch is engaged. This solenoid is fed 12V from the TCC switch portion of the VRV and is grounded through the transmission's governor pressure switch.

On all V6 diesel EGR systems, the vacuum from the vacuum pump is modulated by the Vacuum Regulator Valve (VRV) mounted on the injection pump, as it is on the V8 diesels. The amount of EGR valve opening is further modulated by a Vacuum Modulator Valve (VMV). The VMV allows for an increase in vacuum to the EGR valve as the throttle is closed, up to the switching point of the VMV. The system also employs an VRV valve in the same manner as the V8 diesel system.

TESTING DIESEL EGR SYSTEM

Vacuum Regulator Valve (VRV)

The VRV is attached to the side of the injection pump and regulates vacuum in proportion to throttle angle. Vacuum from the vacuum pump is supplied to port A and vacuum at port B (see illustration) is reduced as the throttle is opened. At closed throttle the vacuum is 15 in. Hg.; at half throttle, 6 in. Hg.; at wide open throttle there should be zero vacuum.

Exhaust Gas Recirculation (EGR) VALVE

Apply vacuum to the vacuum port. On

V8 engines, the valve should be fully open at 10.5 in. Hg. and closed below 6 in. Hg. On V6 engines, the valve should be fully open at 12 in. Hg. and closed below 6 in. Hg.

Response Vacuum Reducer (RVR)

Connect a vacuum gauge to the port marked "To EGR valve or TCC solenoid". Connect a hand operated vacuum pump to the VRV port. Draw 15 in. of vacuum on the pump and the reading on the vacuum gauge should be .75 in. Hg. lower than the vacuum pump reading on all except High Altitude V8 engines. On High Altitude V8 engines ONLY, the reading should be 2.5 in. Hg. lower.

Exhaust Pressure Regulator Valve (V6 Diesels)

Apply vacuum to the vacuum port of the valve. The valve should be fully closed at 12 in. Hg. and open below 6 in. Hg.

Vacuum Modulator Valve (VMV)

To test the VMV, block the drive wheels, and apply the parking brake. With the shift lever in Park, start the engine and run at a slow idle. Connect a vacuum gauge to the hose that connects to the port marked "MAN". There should be at least 14 in. Hg. of vacuum. If not, check the vacuum pump, VRV, RVR, solenoid, and all connecting hoses. Reconnect the hose to the "MAN" port. Connect a vacuum gauge to the "DIST" port on the VMV. The vacuum reading should be 12 in. Hg. except on High Altitude cars, which should be 9 in. Hg.

Catalytic Converters

Two main types of converters are used on today's vehicles. The first is an oxidation type converter containing two precious (noble) metals, platinum and palladium to effectively catalyze the oxidation of the hydrocarbons (HC) and carbon monoxide (CO). The second type converter used is considered a three-way catalyst, containing plat-

Pellet type catalytic converter

Sectional view of three-way catalytic converter

inimum and rhodium in the front part of the converter to reduce the oxides of nitrogen (NO_x), while platinum and palladium are used in the rear section to oxidize the hydrocarbons (HC) and carbon monoxide (CO), as was done in the two-way converters.

Oxidizing Catalytic Converters

These converters do not operate unless there is sufficient oxygen in the exhaust stream. It is extremely important that the proper amount of oxygen is supplied at all times. This is accomplished by a secondary air source, provided by either an air pump system or a pulse air type system. The catalytic converter system is protected by several devices that block out the secondary air supply when the engine is laboring under any abnormal hot or cold operating situation, preventing converter overheating and burnout. Converter temperatures are normally between 900 and 1500°F, with peak temperatures around 1800°F, so the converters must be hot to properly perform their functions. Should the converter be

1981 G.M. electric early fuel evaporative heater

supplied too rich a mixture of hydrocarbons (HC), such as would result from a misfiring spark plug or stuck choke valve, along with an oversupply of fresh air, the converter temperature would increase sharply, causing a burnout of the catalyst material.

NOTE: Some computer controlled systems use an air management valve to increase converter efficiency by routing air to the exhaust system under certain conditions.

Three-Way Catalytic Converters

The three-way catalytic converters use a combination of catalysts which produce two different chemical reactions, oxidation and reduction. By adding fresh air to the unburned hydrocarbons (HC) and carbon monoxide (CO) within the converter, the oxidizing or combustion process takes place.

Just the reverse process is required to lower the oxides of nitrogen (NO_x) emissions. The oxides of nitrogen (NO_x) already contains excessive oxygen and the process of separating the excess oxygen from the nitrogen is called a reducing reaction. This reducing or reduction process is done in the front section of the converter while the oxidizing process is accomplished in the rear section. A fresh air connector is located on the center of the converter shell to add fresh air from the air system as required.

To enable the three-way converter to operate properly, the engine air/fuel ratio must be held within a tight range, called a "Stoichiometric" range. This is accomplished with the use of the closed loop, feedback fuel management systems incorporating the latest electronic controls.

TESTING

There is no way to test a catalytic converter in the field to see if it is actually working. Tailpipe readings may be used to set carburetor idle mixtures, when the car maker requires it, but

19 EMISSION CONTROLS

taking a tailpipe reading to determine if the converter is working is not possible.

The one field check that is recommended in all cases is to inspect for mechanical damage. If a converter gets overheated, the catalyst can melt and block the exhaust. Pellets or pieces of the catalyst may even come flying out the tailpipe while the engine is running. If this happens, the pellets or the entire converter must be changed.

Checking for a melted converter that restricts the exhaust can be done with a vacuum gauge connected to the engine. Run the engine at about 2500 rpm in Park or Neutral. If the vacuum reading slowly drops, it indicates a buildup of pressure in the exhaust.

The use of leaded fuel will slowly destroy the efficiency of the catalyst. If used long enough, leaded fuel can even cause catalyst plugging to the point where the engine will not run. If you know that a car has been run on several tanks of leaded fuel, then you can be sure that the catalyst is ruined. The only thing you can do is change the catalyst or install a new converter.

NOTE: Do not change the catalyst if the car has been run on only one tank or less of leaded fuel. Switching back to unleaded will allow the catalyst to recover and be almost as efficient as it was.

CONVERTER OVERHEAT PROTECTION

Some cars have overheat protection systems for the converter. Ford Motor Co. sometimes uses a heat sensitive switch mounted in the floorpan above the converter. The switch turns a vacuum to the air pump bypass valve. When the vacuum is shut off the bypass valve dumps the pump air into the atmosphere, diverting the air away from the exhaust system. Without the air in the exhaust, the converter's catalytic heat reaction slows and the system cools down.

Chrysler Corporation cars use an overheat protection system that holds the throttle open to prevent high speed closed throttle deceleration. Any engine decelerating on closed throttle is usually running rich, because the high vacuum pulls so much fuel out of the carburetor bowl through the idle circuit. This rich mixture can cause the catalytic reaction to speed up, increasing the heat generated to dangerous levels. Holding the throttle open slightly while decelerating allows more air into the engine and eliminates the problem.

The Chrysler catalyst protection system uses a solenoid on the carburetor that is identical to an anti-dieseling solenoid. The solenoid is controlled by an electronic speed switch and only comes on when the engine speed is above 2000 rpm. When the solenoid is on, its stem extends to the equivalent of a 1500 rpm fast idle setting. If the driver takes his foot off the throttle, the throttle does not close, but rests against the extended solenoid stem. The solenoid goes off below 2000 rpm so that the engine doesn't run away with the car in traffic.

To test the system put the transmission in Park or Neutral and operate the throttle from under the hood. Slowly increase the engine speed until it is above 2000 rpm. The solenoid stem should extend. As the speed drops below 2000 rpm, the stem should retract.

NOTE: Because the catalytic converter operating temperature increases with the engine idling, DO NOT allow any catalyst-equipped vehicle to idle for more than five minutes without increasing the engine speed to allow the converter to cool down.

Exhaust Heat Riser Valves

Exhaust heat riser valves have been used for many years to force part of the engine exhaust through a passageway under the intake manifold and preheat the fuel mixture to allow better atomization of the fuel droplets. The heat valve was spring loaded into the closed position, but heat would make the spring relax so that during high speed operation or after

warmup the exhaust would push it open.

Now, many engines use vacuum-operated heat valves, controlled by a vacuum switch that is sensitive to engine temperature (although the above system, controlled by a thermostatic spring, is still used in some engines). Ford calls their system simply a vacuum operated exhaust heat valve. General Motors refers to theirs as Early Fuel Evaporation, and Chrysler calls theirs a Power Heat Control Valve.

On all these systems, manifold vacuum is used to close the valve, and force the exhaust gases through the crossover passage in the intake manifold. All the systems have some kind of temperature valve that shuts the vacuum off when the engine warms up. Both Chrysler and Ford products use a simple coolant temperature-sensitive vacuum switch mounted on the intake manifold coolant passage. The Chrysler switch has two hose connections. It actually does triple duty because it also controls the vacuum supply to the idle enrichment system and the air switching valve. Ford's vacuum switch has three hose connections, but one of them is a vent with a filter to keep the dirt out.

General Motors cars use either a coolant vacuum switch, or a vacuum solenoid connected to an oil temperature switch. The coolant vacuum switch has two hose connections and a vent when it controls the heat valve only. When it is tied into other emission control systems, it can have as many as five hose connections, and a vent. Many General Motors cars also have a check valve in the hose so that vacuum will be trapped in the heat valve actuator when the engine is accelerated. This keeps the heat valve

Chrysler Air Aspirator system

in the closed position and prevents a rattle.

TESTING

Testing the vacuum operated heat riser valve is a matter of making sure it closes and opens freely. You can move it by hand to see if it works, on a warm engine. On a cold engine, the valve should be closed, and disconnecting the hose should allow it to open (engine idling). On a cold engine, there should be vacuum at the vacuum actuator, and on a warm engine the vacuum should be shut off.

GM Early Fuel Evaporation (EFE) System

The electrically operated EFE system

used on some 1981 and later GM engines performs the same function as the vacuum operated heat riser on other engines, which is to preheat the engine induction system during cold driveway. Rapid heating is desirable because it provides quick fuel evaporation and more uniform fuel distribution to aid cold driveability.

The electrically heated EFE system has a ceramic heater grid located underneath the primary bore(s) of the carburetor which is part of the carburetor insulator. When the ignition is turned on and engine coolant temperature is low, voltage is applied to the EFE relay, which in turn transfers the voltage to the EFE heater in the ceramic grid. When temperature increases, a thermal valve switch de-energizes the relay and the heater is turned off.

TESTING EFE HEATER

To check the resistance of the heater, turn the ignition OFF, disconnect the heater electrical connector, using a ohmmeter, measure the resistance across the two terminals of the heater connector. If resistance is under 2 ohms, the heater is good. If not, replace the heater.

Air Injection Systems

On these systems, a belt-driven air pump supplies air to small tubes positioned in the exhaust port near each exhaust valve. The air mixes with any unburned hydrocarbons in the exhaust and the hydrocarbons burn up in the exhaust system. On late model engines, air may not be pumped to every exhaust port, and some engines have only a single air injection fitting on the exhaust pipe near its connection to the exhaust manifold. Air injection systems are frequently used on engines with catalytic converters so that the converter gets enough air to keep the reaction going.

AIR SWITCHING VALVE CROSS SECTION (AIR TO CONVERTER OPERATION)

Typical GM air switching valve (ASV) assembly

Plumbing on air injection systems varies considerably. At first, all the plumbing was external, with individual tubes inserted into each exhaust port either through the cylinder head or the exhaust manifold. Now many engines have internal passageways to duct the air to the exhaust port. A check valve is used between the pump and the exhaust port nozzle to keep hot exhaust gases from traveling up the plumbing and destroying the pump. Some V8 and V6 engines use two check valves.

Vacuum differential valve VDV

EXTERNAL MUFFLER TYPE

INTERNAL MUFFLER TYPE

General Motors Diverter Valves

An anti-backfire valve, also called a bypass valve or divert valve, is used between the pump and the check valve. Usually, the diverter valve is mounted on the pump or near it. A small sensing hose connects the diverter valve to intake manifold vacuum. When the vacuum rises during deceleration, the diverter valve opens and vents the pump air into the atmosphere. This prevents an over-rich fuel mixture in the exhaust system from exploding or backfiring out the tailpipe. Some systems have a delay valve, similar to a spark delay valve, in the sensing hose. This delays for a few seconds the drop in vacuum when the throttle closes, so that the air is not dumped every time the driver takes his foot off the throttle in traffic.

Temperature controls are also used in the sensing hose hookup. Usually, the temperature valve shuts the vacu-

um off when the engine is cold, so that the pump air doesn't go to the engine exhaust ports until the engine warms up. Some cars have a temperature sensor mounted under the car above the catalytic converter. If the converter overheats, the sensor turns off a solenoid which shuts off the air to the diverter valve. The diverter valve then goes to the dump position, shutting off the air to the exhaust to keep the converter from melting or burning up.

Ford Motor Company 4-cylinder, V6, and some inline 6 engines use a unique air bypass valve, with two small sensing hoses connected to it. Each of the hoses connects to one side of a diaphragm in the valve. The hose on the body of the valve connects to manifold vacuum, and the hose closer to the end connects to a separate on-off valve. The diaphragm has a small

hole so that the vacuum or pressure on each side will equalize. As long as the end chamber is sealed by the separate valve being closed, nothing happens, and the air flows through the bypass valve on the way to the exhaust ports. But if the separate valve is opened it admits atmospheric pressure to one side of the diaphragm, and the vacuum on the other side moves the bypass valve to the dump position, exhausting the pump air into the atmosphere. Two types of separate valves are used, one of them an electric solenoid operated valve, and the other a vacuum-operated valve.

AIR PUMP TESTS

CAUTION

Do not hammer on, pry or bend the pump housing while tightening the drive belt or testing the pump.

Before proceeding with the tests, check the pump drive belt tension. If the belt squeals when the engine is running, the pump may be dragging or seized. Remove the belt and turn the pump by hand to check for seizure. Disregard any chirping, squealing, or rolling sounds from inside the pump when turning it by hand, as these are normal.

Check the hoses and connections for leaks. Hissing or a blast of air is indicative of a leak. Soapy water, applied lightly around the area in question, is a good method for detecting leaks. To test air output, disconnect the air hose from the pump wherever it is convenient. If you disconnect it from one check valve on a V8 or V6, the other hose should also be disconnected and plugged for the test. Run the engine at idle and feel the blast of air from the hose with your hand. Increase the engine speed to 1500 rpm and feel the blast of air again. If the blast increases and is steady, the pump is okay.

Pump Noise Diagnosis

The air pump is normally noisy. As engine speed increases, the noise of the pump will rise in pitch. The rolling sound the pump bearings make is normal. However, if this sound becomes objectionable at certain speeds, the pump is defective and will have to be replaced. A continual hissing sound from the air pump pressure relief valve at idle indicates a defective valve. Replace the relief valve.

If the pump rear bearing fails, a continual knocking sound will be heard. Since the rear bearing is not separately replaceable, the pump will have to be replaced as an assembly.

DIVERTER (ANTI-BACKFIRE) VALVE TEST

Detach the hose, which runs from the bypass valve to the check valve. Connect a tachometer to the engine. With the engine running at normal idle speed, check to see that air is flowing from the bypass valve hose connection. Increase the engine speed to 1500-2000 rpm and allow the throttle to snap shut. The flow of air from the bypass valve at the check valve hose connection should stop momentarily and air should then flow from the exhaust port on the valve body or the silencer assembly.

Let the throttle snap shut several times. If the flow of air is not diverted into the atmosphere from the valve exhaust port or if it fails to stop flowing from the hose connection, check the vacuum lines and connections. If these are tight, either the bypass valve or one of the accessory valves in the small sensing hose is defective and must be replaced. A leaking diaphragm will cause the air to flow out both the hose connection and the exhaust port at the same time. If this happens, replace the valve.

NOTE: Late model systems should stop flowing at idle, as described earlier. If not, the bypass valve or accessory valve is defective.

CHECK VALVE TEST

Remove the hose from the check valve. With the engine running at 1500 rpm in Park or Neutral, hold the back of your hand near the check valve to test for exhaust gas leakage. If the valve leaks, it must be replaced.

NOTE: Vibration and flutter of the valve at idle is a normal condition caused by exhaust pulsations. It does not mean that the valve is defective.

VACUUM DIFFERENTIAL VALVE TEST

Disconnect the small sensing hose at the bypass valve and connect a vacuum gauge to the hose. With the engine idling in Park or Neutral, the gauge should read full manifold vacuum. Run the engine at a steady 2500 rpm in Park or Neutral, and release the throttle. As the engine decelerates, the vacuum gauge should drop close to zero, then return to full manifold vacuum as the engine speed drops to idle. If not, the VDV is defective and must be replaced.

Air pump system using a timed air by-pass valve vacuum vent

Catalyst cars use a different air bypass valve, with small hose connecting to the end.

NOTE: The small hose nozzle should be connected to manifold vacuum.

Chrysler Air Aspirator System (AAS)

Chrysler Corporation cars which use this system have done away with the air pump. The complete air aspirator system consists of a hose from the clean side of the air cleaner, the aspirator valve mounted on top of the engine, and a tube connecting the valve with the exhaust manifold. The suction in the exhaust draws in air through the air cleaner and this extra air helps the catalytic converter burn up the pollutants. The aspirator valve is similar to the check valve used with all air pump systems. It keeps the ex-

haust from flowing back into the air cleaner, but allows clean air to go into the exhaust.

TESTING AAS VALVE

Testing the air aspirator valve is done by disconnecting the hose from the air cleaner and checking for slight suction at idle with a piece of paper over the end of the valve. Speeding the engine up slightly will show if the valve is leaking. Exhaust should not come out of the valve. Vibration of the valve diaphragm is normal due to exhaust impulses.

GM Pulse Air Injection System

This system is similar to Chrysler's Air Aspirator. A hose from the clean side of the air cleaner connects to the pulse air valve. Tubes connect the pulse air valve to each cylinder's exhaust port. Suction in the exhaust draws fresh air from the air cleaner into the exhaust, and the air helps the catalytic converter burn up the pollutants. The pulse air valve consists of four or six check valves built into a housing. It allows each exhaust port to suck in fresh air independently of the other ports. The check valves only open when there is suction in the exhaust. If there is any back pressure, the check valves close to prevent exhaust flow back into the air cleaner. On some applications the pulse air valve is connected to only three of the

four exhaust ports on a 4-cylinder engine.

TESTING PULSE AIR INJECTION SYSTEM

To test the pulse air valve, remove the rubber hose from the valve and run the engine at idle. You should notice a slight pulsation of the valves, drawing air into the exhaust. With the engine off, use a vacuum pump to apply 15 in. Hg. vacuum. The vacuum will slowly bleed off, but as long as it takes more than two seconds to fall from 15 in. to 5 in. Hg. the valve is okay. If the vacuum falls off faster than that, the valve is leaking and must be replaced. On the V6, the two pulse air valves must be tested individually. Disconnect the solenoid valve (if used) from the front pulse air valve before testing that valve on the V6.

Chrysler Pulse Air Feeder (PAF) System

The PAF system supplies secondary air into the exhaust system between the front and rear catalytic converters, which promotes oxidation of exhaust emissions in the rear catalytic converter. The system consists of a pulse air feeder, which contains two reed valve assemblies, a hose which links the pulse air feeder to the air cleaner, and a tube which runs from the feeder to the exhaust system. At the bottom of the feeder there are two tubes, one which runs into the oil sump and one which connects to No. 3 cylinder crankcase above the oil level. The main reed valve is actuated by a diaphragm in the feeder which, in turn, is activated by the pressure pul-

sation generated by the reciprocating motion of No. 3 piston. This pressure pulsation is fed to the diaphragm by a seal cover in the crankcase, which acts much like the human body's diaphragm when a person is breathing.

TESTING PAF SYSTEM

With the engine running, remove the hose at the air cleaner which runs to the feeder and check for vacuum. If no vacuum is present, check the hoses for leaks and evidence of oil leaks. Periodic maintenance service for the system is not required.

Air Management System (MAIR)

The Air Management System is found on 1981 and later GM gasoline engines. The system helps reduce HC and CO emissions in the same basic manner of a typical air pump-type air injection system, except that the MAIR system is controlled by signals from the electronic control module (ECM).

When the engine is cold, the ECM energizes an Air Control Solenoid. This allows air to flow to an Air Switching Valve, which is energized to direct air to the exhaust ports. On a warm engine or when in "Closed Loop" operation, the ECM de-energizes the Air Switching Valve, directing air between the beds of the catalytic converter. This provides additional oxygen for the oxidizing catalyst to decrease the HC and CO levels. If the Air Control Valve detects a rapid increase in manifold vacuum (deceleration, etc.), certain operating modes (wide open throttle, etc.),

or the ECM self-diagnostic system detects any problem in the MAIR system as a whole, air is diverted (divert mode) to the air cleaner or directly into the atmosphere.

The air flow and control hoses transmit pressurized air to the catalytic converter or to the exhaust ports through internal (intake manifold) passages or external piping. The check valves prevent backflow of exhaust gas into the air distribution system. The valve prevents backflow when the air pump "bypasses" at high speed and loads, or in case the air pump malfunctions.

NOTE: Due to the complex nature of modern electronic engine control systems, comprehensive diagnosis and testing procedures fall outside the confines of this repair manual. For complete information on diagnosis, testing and repair procedures concerning all modern engine and emission control systems, please refer to *Chilton's Guide To Electronic Engine Controls*.

Ford Pulse Air (Thermactor II) System

Some Ford engines are equipped with an air injection system which does not use an air pump. Instead, natural pulses present in the exhaust system are used to pull the air into the system through the pulse air valves. The pulse valve is connected to the exhaust manifold by a tube and to the air cleaner or silencer with a hose. Make sure air can flow freely through the air cleaner or silencer to the check valve.

Electronic Engine Controls 20

ENGINE ELECTRONICS

In the latter part of the 1960's, Robert Bosch introduced the first true electronically controlled engine with an on-board computer. Today, almost every car produced has some kind of electronic control. The once mechanically controlled engine functions are all but extinct.

The first system, Bosch D-Jetronic, is comprised of electrically energized fuel injectors in which the injection time is controlled by an electronic control unit (ECU). The early system delivered a basic quantity of fuel and varied from this point depending upon engine load, engine speed and engine temperature.

Since the early days of ECU, the controls have become more complex, with a much greater amount of computer memory and even the ability to learn.

In this section the topics will include different types of electronically controlled fuel induction, spark control, the sensors and switches that provide the ECU with information, other non-engine related controls that the ECU might supply and some ECU self-diagnostics.

The most common fuel induction system with an ECU is electronic fuel injection. In this system fuel can be delivered many different ways. One of which is the single point injection (SPI) where one or two injectors are mounted on a throttle body assembly. Fuel is delivered constantly through the injector(s), but in varying quanti-

ties. The SPI system very much resembles a carbureted system. SPI is more commonly known as throttle body injection (TBI). Another fuel injection system is multi-point injection (MPI). This system supplies one injector for each cylinder, usually positioned in the intake manifold, just above the intake valve. In MPI, fuel can be injected in two ways. One is to energize a group of injectors, thus atomizing fuel in the intake manifold and storing it for a short time until the intake valve opens. The second way is to sequentially energize each cylinder's injector as the intake valve is opened. This injection is the more efficient, effective and more complex system.

Another fuel induction system utilizing an ECU is the feedback carburetor (FBC). A conventional carburetor is still used but it has a more precise air/fuel mixture control which is achieved through an integral mixture control solenoid. The solenoid is energized on and off by the ECU to maintain mixture demand. The ECU calculates air/fuel mixture demand changes by the data it receives through remote sensors. The most important sensor (and makes the system possible) is an oxygen (O_2) sensor (which will be discussed later in this section). The ECU monitors the exhaust gases for rich/lean conditions by way of the O_2 sensor and, in turn, controls the air/fuel mixture by increasing or decreasing the duty cycles (on and off) to the mixture control solenoid for an optimum 14.7:1 air/fuel ratio.

ECU Self-Diagnostics

The ECU can detect a malfunction or

abnormality in the sensors or in the ECU itself and display a warning light on the instrument panel when it does. When this occurs, the ECU stores a trouble code for future system diagnosis. If the problem is severe enough to where it inhibits closed loop operation, the ECU will assume a backup system. This fail-safe circuit is pre-programmed into the ECU for minimal driveability operation so the vehicle can be driven to a nearby service facility. The trouble codes are usually a two digit number identified by the number of diagnostic LED or check engine light flashes. The trouble codes assist the service technician in isolating a faulty circuit or component within the system.

Electronic Data Sensors

The engine control system consists of various data sensors. Although data sensor names and applications vary from system to system, the most common input sensors/switches are:

- oxygen (O_2) sensor
- coolant temperature sensor
- manifold air pressure (MAP) sensor
- vehicle speed sensor (VSS)
- throttle position sensor (TPS)
- engine speed reference or distributor reference (rpm)
- air flow sensor
- air intake temperature sensor
- crankshaft sensor
- detonation (knock) sensor
- throttle body temperature sensor
- throttle idle switch
- transmission or drive switch
- a/c compressor clutch switch

Electronic engine control components

- power steering pump switch
- altitude or barometric pressure sensor
- wide open throttle switch

Electronically Controlled Devices

Some of the output devices that the ECU may control vary from system to system, but the most common output or ECU controlled devices are:

- fuel injector(s)
- air/fuel mixture solenoid
- fuel pump relay
- a/c compressor clutch relay
- idle air control (IAC) valve
- idle speed control (ISC) motor
- ignition spark/timing
- canister purge solenoid
- torque converter clutch solenoid (automatic transmission)
- air management system (air induction)
- idle-up or throttle kicker solenoid
- alternator field control (charging system)
- turbocharger boost wastegate
- cooling fan relay

Component Description

THROTTLE BODY

The throttle body, in most fuel injected systems, is usually an aluminum housing that consists of one or two throttle blades which are attached to a throttle shaft. The housing has a throttle position sensor (TPS) sensor, idle air control motor and, in some cases, throttle body temperature sensor. On SPI systems, the housing also has an injector(s) and (in some cases) a fuel pressure regulator. The throttle body throttle blade controls the amount of air that enters the engine as well as the amount of vacuum.

ELECTRONIC CONTROL UNIT (ECU)

The ECU monitors and controls all engine control functions. The ECU consists of input and output devices, a central processing unit, a power supply and various memory banks. The input and output devices of the ECU convert electrical signals received by the data sensors and switches to the digital signal that are used by the central processing unit. The central processing unit receives digital signals that are used to perform all mathematical computations and logic

Electronic engine control component locations

Throttle body - TBI

functions necessary to deliver proper air/fuel mixture. The central processing unit is also responsible for calculating spark timing information. The main source of power that allows the ECU to function is generated from the battery of the vehicle and transported through the ignition system. The memory bank of the ECU is programmed with exact information that is used by the ECU during the open loop mode. This data is also used when a sensor of other component fails, allowing the vehicle to be driven to a repair facility.

CALIBRATION ASSEMBLY OR PROM (PROGRAMMABLE READ ONLY MEMORY)

Some vehicle manufactures use one ECU for several different model vehicles. This interchangeable ECU is possible through the use of a calibration assembly or prom. Information about the vehicle's engine, transmission, body and drive axle ratio are programmed and permanently stored into the assembly. If the battery supply should become disconnected from the ECU, the data stored into the assembly is not lost.

ELECTRONIC SPARK CONTROL (ESC)

The vehicles equipped with an ESC have the ability to change the ignition timing under any and all operating conditions. Data from various remote sensors (coolant temperature, throttle position, rpm, etc.) is transmitted to the ESC. The ESC computes the information and triggers the ignition spark at precisely the right instant. Some ESC systems (ie., turbocharged engines) use a detonation (knock) sensor which senses pre-ignition and

MASS AIR FLOW SENSOR

The mass air flow (MAF) sensor is

only incorporated in some Multi-point fuel injection systems. The MAF sensor is a very complex device which measures the air mass of the engine intake. Because the air mass is always changing with temperature, humidity and altitude, the fuel delivery rate must be adjusted to compensate for these changes so that a precise fuel mixture can be maintained.

14 THROTTLE POSITION SENSOR
15 TBI UNIT

Throttle position sensor (TPS)

Coolant temperature sensor

Oxygen (O₂) sensor

AIR TEMPERATURE SENSOR

The air temperature sensor is located in the air stream of the air flow meter. The sensor supplies incoming air temperature information to the ECU. The ECU uses this data, along with other data, to regulate fuel injection rate.

THROTTLE POSITION SENSOR (TPS)

The TPS can be either a switch (or a combination of switches) or a variable resistor which is much more accurate in throttle position. The switch type

Manifold air pressure (MAP) sensor

Detonation (knock) sensor

TPS consists of switches that open and close at different throttle positions (usually at idle and wide open throttle) and sends the information to the ECU. The variable resistor type receives a reference voltage from the ECU and responds back to the ECU with a proportional voltage directly related to the position of the throttle plate.

ENGINE COOLANT TEMPERATURE SENSOR

The coolant temperature sensor is located in the engine coolant passage, usually located in the intake manifold. The sensor is resistor based and changes resistance as coolant temperature changes. The sensor uses a reference voltage and the output voltage is sent to the ECU. The ECU calculates engine warm up and provides an optimum fuel enrichment when the engine is cold.

OXYGEN (O₂) SENSOR

The O₂ sensor, which is placed in the

exhaust stream, monitors the oxygen content in the exhaust gas. The sensor is mounted in the exhaust manifold and is sometimes internally heated electrically for faster switching to the closed loop mode. The sensor produces a voltage proportional to the oxygen content which represents a lean or rich condition and transmits the information to the ECU. A low voltage condition indicates a lean mixture (high O₂ content) and a higher voltage indicates a rich mixture (low O₂ content). The ECU uses the information, along with other sensor data, and changes the fuel induction as required.

CYLINDER HEAD TEMPERATURE SENSOR

The cylinder head temperature sensor monitors the temperature of the cylinder head and transmits the information to the ECU. The sensor is located in the cylinder head and is a temperature sensitive resistive unit known as a thermistor.

VEHICLE SPEED SENSOR (VSS)

The VSS provides vehicle speed data to the ECU in the form of pulse signals. There are many different types of VSS, some using a reed switch installed in the speed meter unit and others using an optical type. In the optical type a light emitting diode (LED) is used to transmit light and photo diode receives the light. A shutter device, which is usually in-line with the speedometer cable, allows the LED light to reach the photo diode in vehicle speed related pulses. The reed switch type relies on a reed switch that opens and closes by way of a rotating magnet. The magnet rotates proportionally with the vehicle speed.

MANIFOLD AIR PRESSURE (MAP) SENSOR

The MAP sensor is a device that monitors manifold absolute pressure. The sensor is mounted remotely and senses vacuum through a connecting hose. The MAP sensor has a reference voltage from the ECU and transmits remaining voltage to the ECU to calculate engine load. The ECU uses this data along with other data to determine fuel demands.

DETONATION (KNOCK) SENSOR

The detonation sensor generates a

Crankshaft position sensor

signal when pre-ignition (knock) occurs in one or more combustion chambers. The sensor is made of a material that is sensitive to oscillation that the engine knock produces and sends signals to the ECU. The ECU, in turn, delays the ignition signal which retards the ignition timing and continues to do this until the engine knock ceases.

CRANKSHAFT (REFERENCE MARK) SENSOR

The crankshaft sensor may be located at either the rear of the engine, at the flywheel or at the front of the engine, near the crankshaft pulley. The sensor detects crankshaft position in relation to top dead center and transmits the signals to ECU.

IDLE SPEED CONTROL (ISC) MOTOR

The ISC is sometimes included on a feedback carburetor system and mounted to the side of the carburetor. The motor driven ISC would maintain a steady idle by way of the ECU. When an added load is put on the engine (air conditioning or when vehicle is in drive) the ECU could increase the idle via the ISC by extending a plunger which would open the throttle valve.

AIR/FUEL MIXTURE SOLENOID

The air/fuel mixture solenoid on feedback carburetor operates in conjunction with the fixed metering jets and/or the manually adjustable idle speed mixture screw. The ECU energizes and de-energizes the solenoid in the closed loop mode. The solenoid usually controls a fixed air bleed and/or fuel discharge port.

Idle speed control (ISC) motor

Air/fuel mixture solenoid

IDLE AIR CONTROL (IAC)

The IAC in a fuel injection system controls the air flow around the throttle plate by extending and retracting a bypass valve in the bypass port. The ECU controls the valve by sending voltage pulses called counts or steps to increase or decrease the bypass air flow, thus increasing and decreasing the idle speed.

FUEL INJECTOR

Throttle Body Type

The fuel injector is an electric solenoid controlled by the ECU. The ECU controls the injector by varying voltage pulse widths. When electrical current is supplied to the injector a spring loaded ball is lifted from its seat. This allows fuel to flow through spray orifices and deflects off the sharp edge of the injector nozzle. This action causes the fuel to form a 45° cone shaped spray pattern before entering the air stream in the throttle body.

Multiport Type

The fuel injector is an electric solenoid controlled by the ECU. The ECU controls the injector by varying voltage pulse widths. When electrical current is supplied to the injector, the armature and pintle move a short distance against a spring, opening a small orifice. Fuel is supplied to the inlet of the injector by the fuel pump, then passes through the injector,

DUAL TAPER VALVE

BLUNT PINTLE

Idle air control (IAC) valves

Fuel Injector - TBI type

around the pintle and out the orifice. Since the fuel is under high pressure, a fine spray is developed in the shape of a hollow cone. The injector, through this spraying action, atomizes the fuel and distributes it into the air entering the combustion chamber.

TORQUE CONVERTER CLUTCH (TCC) SOLENOID

The TCC solenoid is used on some automatic transmission, which allows for better fuel economy. When certain engine and vehicle speeds have been met, the ECU energizes the solenoid. This allows transmission fluid to flow into passages in the torque converter,

Engine Electronic Operations

IGNITION SYSTEM

The logic in a computerized system's program selects the method of spark timing control. During engine starting, spark timing is controlled by the mechanical setting of the distributor. Once the engine is running, spark timing is turned over to the ECU. This scheme ensures that the car will start regardless of whether the electronic control system is working or not.

The goal of electronic spark timing is to produce maximum engine power by adjustment the advance of the ignition firing in relationship to top dead center (TDC). The spark timing can be chosen to produce the best engine power with input variables of engine rpm, engine coolant temperature, initial and operating manifold or barometric pressure.

The total spark advance is determined by computing the information received from the various engine sensors which affect spark timing. The processor will then adjust the timing according to information that has been calibrated in it. The processor has programmed into it specific information on:

Warm-Up Spark Advance—this is used when the engine is cold, since a greater amount of advance is required while the engine warms up.

Special Spark Advance—to improve fuel economy during steady driving conditions.

Spark Advance Due to Barometric Pressure—this is used when barometric pressure exceeds a preset calibrated amount.

All of this information is then added together and the initial mechanical advance (if equipped) is subtracted to determine the final spark advance.

The processor receives a timing pulse from a sensor which indicates crankshaft position for top dead center and engines rpm. The processor makes a decision based upon this information and the information that was calibrated into it. at that time, the computer sends a pulse to the ignition actuator circuit which opens the ignition coil primary circuit to generate a secondary voltage pulse to fire the spark plugs. In some cases, the circuitry to open the primary of the coil may be in the computerized controller. The spark selection is performed mechanically by the distribu-

tor and rotor contacts as it is done in a non-electronic controlled system.

The ignition timing works along with electronic fuel control to control emissions and provide for optimum fuel economy and driveability because engine power, fuel economy and emissions are dependent on spark advance of the engine timing.

The system just described is considered to operate in open-loop. There are some electronically controlled ignition systems which receive an input from a knock sensor. These systems operate in a closed-loop mode which allows the ignition system to monitor the engine for mechanical changes, such as engine knock.

Engine knock is a condition where the air/fuel mixture in the cylinder does not burn normally. the pressure rise during this burning is so rapid compared to normal combustion that it is accompanied by an audible "knock".

Through some low level knock is acceptable, it is important to avoid excessive knock. To control engine knock, a knock sensor is installed in the engine or intake manifold. This helps to detect excessive engine knock.

The knock sensor is a tuned accelerometer and produces an output voltage depending on the amount of engine vibration occurring in a certain frequency band. When the processor receives a signal from the knock sensor, it retards the spark advance until the knocking stops and then starts increasing it again. This cycle is repeated as long as engine knock occurs.

FUEL CONTROL

In order for the processor to control fuel, it requires a sensor or sensors to monitor the state of the engine, and one or more actuators to do the actual controlling. The sensors measure: exhaust gas oxygen, manifold or barometric absolute pressure, engine rpm and speed, inlet air and coolant temperatures. Actuators are energized to control the air/fuel ratio.

The primary purpose of this control system is to maintain air/fuel ratio at or near 14.7:1 ratio. This is accomplished in two modes (during normal engine operation) open and closed loop. The electronic fuel control system can operate in closed loop only when certain conditions are satisfied. Open loop mode is employed whenever these conditions are not satisfied. However, for either mode, the exhaust emissions will satisfy federal requirements if the average air/fuel ratio is held within the tolerance limits.

Fuel Injector - MFI type

Torque converter clutch (TCC) solenoid

which causes the converter to lock up. This lockup is similar to a direct connection made possible in a manual transmission.

FUEL PUMP RELAY

The fuel is supplied under pressure, usually by an electric fuel pump. The ECU controls the fuel pump relay, which controls the fuel pump operation. When the ignition is switch ON, the fuel pump relay is energized and the fuel pump is activated. The pump primes the fuel system with fuel to a pre-determined pressure.

Electronic spark timing system

In addition to open and closed loop control modes, a practical fuel control system has other operating modes depending on engine conditions. These handle such conditions as starting, rapid acceleration or heavy load, sudden deceleration, idling, etc.

An automotive engine has various operating modes as the operating conditions change. Preprogrammed into the processor, control logic determines the operating mode from the engine conditions that exist. From these engine conditions, the system determines which operating modes are to be performed.

There are seven different engine operating modes which affect fuel control: engine crank, engine warmup, open loop, closed loop control, hard acceleration, deceleration and idle. The program for mode control logic determines the engine operating mode by reading various sensors.

When the ignition switch is initially switched on, the mode control logic automatically selects an engine-start control scheme which provides the low air/fuel ratio required for starting the engine. Once the engine rpm rises above the cranking value, the controller identifies the engine-started mode and passes control to the program for the engine warm-up mode. This operating mode keeps the air/fuel ratio low to prevent engine stall during cool weather until engine coolant temperature rises above a preset value.

When the coolant temperature rises, the mode control logic directs the system to operate in the open loop control mode until a certain time has elapsed and the exhaust gas sensor warms up enough to provide accurate readings. This condition is detected by monitoring the exhaust gas sensor's output for voltage readings above a certain minimum air/fuel mixture voltage set point. When the sensor has indicated a rich mixture a certain number of times (depending on calibration), and after the engine has been in open loop for a specific time, the control mode logic selects the closed loop mode for the system.

Solid state ignition system

Distributor pick-up coil and armature assembly

The engine remains in the closed loop mode until either the exhaust gas sensor cools and fails to switch (from rich to lean) for a certain length of time, or a hard acceleration or deceleration occurs. If the sensor cools, the control mode logic selects the open loop mode again.

During hard acceleration of heavy engine loads, the control mode logic chooses a scheme which provides a rich air/fuel mixture for the duration of the acceleration or heavy load. This scheme provides maximum power, but poor emissions control and poor fuel economy. After the need for enrichment has passed, control is returned to either open or closed loop depending on the control mode logic selection conditions that exist at that time.

During periods of deceleration, the air/fuel ratio is increased to reduce emissions of HC and CO due to unburned fuel. When idle conditions are present, control mode logic passes system control to the idle speed control mode. In this mode, the engine speed is controlled to reduce engine roughness and stalling which might occur because the idle load has changed due to air conditioner compressor operation, alternator operation, or gear-shift positioning from PARK or NEUTRAL to DRIVE.

Engine Crank

While the engine is being cranked,

the fuel control system must provide an intake air/fuel ratio anywhere from 2:1 to 12:1, depending on engine temperature. Low temperatures affect the carburetor's ability to atomize or mix the incoming air and fuel. At low temperature, the fuel tends to form into large droplets. The larger fuel droplets tend to increase the apparent air/fuel ratio because the amount of usable fuel in the air is reduced, therefore, the system must provide a decreased air/fuel ratio to provide the engine with a more combustible air/fuel mixture. The engine temperature is read by the processor through an analog to digital converter from a temperature sensor in the engine water coolant passage. The processor's calibration determines what the proper air/fuel ratio must be at that temperature. The air/fuel is determined and controlled as in the open loop mode.

Engine Warm-up

While the engine is warming up, an enriched air/fuel ratio is still needed to keep it running smoothly, but the required air/fuel ratio changes as the temperature increases. Therefore, the fuel control system will stay in the open loop mode, but the air/fuel ratio commands continue to be altered due to the temperature changes. The emphasis in this control mode is on rapid and smooth engine warm-up. Fuel economy and emission control are still a secondary concern. The controller determines the warm-up time period based on the coolant temperature when the warm-up mode was selected. Naturally, an initially cold engine requires a longer warm-up time than a warm engine. The time allowed by the controller timer is chosen according to the calibration of the processor.

OPEN LOOP CONTROL

Open loop fuel control is used when the engine has not reached a preset operating condition. This condition is sensed by various sensors located in and around the engine, and include engine coolant temperature, air charge temperature, engine time on, etc. After all these preset conditions are met, the system will go into closed loop. During certain operating conditions, such as a wide open throttle condition the system will go back into open loop.

CLOSED LOOP CONTROL

Closed loop fuel control is selected when the engine is warm and the exhaust gas oxygen sensor exceeds its minimum operating temperature. The intake air/fuel ratio is controlled in a closed loop by measuring the ex-

*May Be Different on some Models.

Throttle body injection air and fuel flow

haust gas at the exhaust manifold and altering the input fuel flow rate or the air entering the main metering systems (depending on the type of fuel system used).

ACCELERATION ENRICHMENT (OPEN LOOP)

During periods of heavy engine load, such as wide open acceleration, fuel control is adjusted to provide an enriched ratio to maximize engine power while neglecting fuel economy and emission.

The computer detects this condition by reading the throttle position sensor voltage or the MAP sensor. Low intake manifold vacuum or throttle position corresponds to heavy engine loads. The fuel control system controller responds by increasing the amount of fuel to enter the intake manifold or to decrease the amount of air in the main metering system. This enrichment allows the engine to operate with a power greater than that allowed when emissions and fuel economy are controlled within specifications.

DECELERATION AND IDLE SPEED CONTROL (OPEN LOOP)

During periods of light engine load and high rpm, such as during closed throttle deceleration, coasting or engine idle, the engine requires a very lean air/fuel ratio to reduce excess emissions of HC and CO. Deceleration is indicated by a sudden increase in manifold vacuum and throttle position, indicating a closed throttle. When these conditions are detected by the processor, it computes a change in the amount of fuel required or amount of air entering the main or idle speed passages (depending on type of fuel system used). On certain engine applications which electronic fuel injection, the fuel may even be turned completely off during closed throttle deceleration.

Idle speed control is used to prevent engine stall during idle. The goal is to allow the engine to idle at as low an rpm as possible, yet keep the engine from running rough and stalling when power takeoff accessories such as air conditioning compressors are turned on.

GENERAL INFORMATION

This section describes in detail, the procedures involved in rebuilding a typical gasoline engine. A rebuilt engine can be expected to give many miles of dependable service only if the proper reconditioning procedures are performed and clearances are kept within the manufacturer's recommended specifications.

The following systems of the gasoline engine should be checked to determine to what degree the rebuilding should be accomplished.

Engine Oil Pressure

The engine oil pressure developed should be compared to the manufacturer's recommended pressure, which is necessary to provide lubricating oil to the engine oil circuits. If the pressure is below specifications, the cause must be located and repaired.

The following wear points should be considered during this determination.

Oil Pump—Check Gear clearances (a new oil pump is a good investment).

Main Bearings and Journals—Check clearances, taper and roundness.

Connecting Rod Bearings and Journals—Check clearances, taper and roundness.

Camshaft and Bearings—Check clearances, taper and roundness.

Rocker Arms, Rocker Arm Shafts—Check arm and shaft wear, ball and seat wear.

Tappets—Check clearances between tappet and bore and for excessive leakdown of hydraulic tappets.

Leakage of oil pressure along external or internal oil galleries or gaskets.

Dilution of the oil by gasoline leakage through failures of the carburetor or mechanical fuel pump.

External damage to the oil pan, causing blockage or movement of the oil pick-up tube, resulting in loss of oil pick-up to the pump.

Engine oil flow diagram—typical

Compression

Compression in an engine is determined by the correct fit and sealing efficiency of the piston and rings against the cylinder walls, the quality of the seal between the valve and its seat and the seal between the cylinder head, head gasket and block. Here are some important check points.

Valve, seat and face—Machine face and seat to original specifications.

Valve guides—The reconditioned seat and face won't hold up long if the valve stem clearance isn't within specifications.

Valve seals—Oil reaching the valve seat will become a solid when it combines with the heat in the combustion chamber. This solid (carbon) will build up and eventually keep the valve from seating.

Cylinder walls—Check for taper, out-of-round and hone to proper cross hatch pattern.

Pistons—Check all dimensions. A poorly fitted piston will shorten the life of the new rings.

COMPRESSION PRESSURE COMPARISON CHART

Minimum pressure is 75% of maximum pressure

Maximum PSI	Minimum PSI	Maximum PSI	Minimum PSI	Maximum PSI	Minimum PSI
134	101	174	131	214	160
136	102	176	132	216	162
138	104	178	133	218	163
140	105	180	135	220	165
142	107	182	136	222	166
144	108	184	138	224	168
146	110	186	140	226	169
148	111	188	141	228	171
150	113	190	142	230	172
152	114	192	144	232	174
154	115	194	145	234	175
156	117	196	147	236	177
158	118	198	148	238	178
160	120	200	150	240	180
162	121	202	151	242	181
164	123	204	153	244	183
166	124	206	154	246	184
168	126	208	156	248	186
170	127	210	157	250	187
172	129	212	158		

NOTE: To Determine if the engine compression is satisfactory, most engine manufacturers require that a complete compression test be done, with the lowest cylinder pressure reading not being less than 75% of the highest reading. Look for uniformity of compression between cylinders, rather than specific compression pressures of an engine.

Cooling System

Maintaining engine temperatures within the specified range is critical to the life of a rebuilt engine. Until new parts mate properly with each other, excessive heat can cause permanent damage or substantially reduce the service life of the reconditioned engine. If the engine is operated at temperatures below normal, the oil may not properly lubricate all of the parts. Some parts that should be checked during the rebuilding process are:

Coolant passages—Should be free of rust and corrosion deposits.

Core plugs—All plugs should be replaced during the rebuilding process.

Hoses—Should be free of cracks, hard spots and oil softened spots.

Thermostat—Check for opening and closing at the specified temperature.

Radiator—Check for leaks and rust or corrosion deposits.

Illustration of cooling system passages being restricted, causing internal engine problems

Pressure cap — Should hold specified pressure, also check the gasket and vent valve operation.

Engine Noises

Engine noises are not only annoying, but indicate conditions inside the engine that can limit the service life of the engine or shut it down completely. Generally, noises are caused by too much clearance between parts or loss of oil supply. Engine noises can be caused by any of the following parts.

- Main bearings
- Connecting rod bearings
- Piston and/or rings

STANDARD TORQUE SPECIFICATIONS AND CAPSCREW MARKINGS

Newton-Meter has been designated as the world standard for measuring torque and will gradually replace the foot-pound and kilogram-meter torque measuring standard. Torquing tools are still being manufactured with foot-pounds and kilo-

gram-meter scales, along with the new Newton-Meter standard. To assist the repairman, foot-pounds, kilogram-meter and Newton-Meter are listed in the following charts and should be followed as applicable.

U.S. BOLTS

24 x 1.5	190 to 240	(260 to 320)	310 to 410	(420 to 550)

CAUTION: Bolts threaded into aluminum require much less torque.

Tools

The tools required for the basic rebuilding procedure should, with minor exception, be those included in a mechanic's tool kit. Accurate torque wrench, micrometers and dial indicators should readily be available to the repairman. Special tools are available from the major tool suppliers. The services of a competent automotive machine shop must also be available.

Precautions

When assembling the engine, any parts that will be in frictional contact must be pre-lubricated, to provide protection on initial start-up.

Any product specifically formulated for this purpose may be used. Where semipermanent locked but removable installation of bolts or nuts is desired, threads should be cleaned and coated with a liquid locking compound. Studs may be permanently installed using a stud mounting compound. Bolts and nuts with no torque specification should be tightened according to size (see chart).

Aluminum has become increasingly popular for use in engines, due to its low weight and excellent heat transfer characteristics. The following precautions should be observed when handling aluminum engine parts.

Never hot-tank aluminum parts.

Remove all aluminum parts (identification tags, etc.) from engine parts before hot-tanking (otherwise they will be removed during the process).

Always coat threads lightly with engine oil or anti-seize compounds before installation, to prevent seizure.

Heli-coil

Never over-torque bolts or spark plugs in aluminum threads. Should stripping occur, threads can be restored according to the following procedure, using Heli-Coil thread inserts.

Tap drill the hole with the stripped threads to the specified size, using the Specified tap.

NOTE: Heli-Coil tap sizes refer to the size thread being replaced, rather than the actual tap size.

Tap the hole for the Heli-Coil. Place the insert on the proper installation tool (see Heli-Coil chart with kit). Apply pressure on the insert while winding it clockwise into the hole, until the top of the insert is one turn below the surface. Remove the in-

stallation tool and break the installation tang from the bottom of the insert by moving it up and down. If the Heli-Coil must be removed, tap the removal tool firmly into the hole, so that it engages the top thread and turn the tool counterclockwise to extract the insert.

Broken Bolts or Studs

Snapped bolts or studs may be removed, using a stud extractor (unthreaded) or locking pliers (threaded). Penetrating oil will often aid in breaking frozen threads. In cases where the stud or bolt is flush with, or below the surface, proceed as follows.

Drill a hole in the broken stud or bolt, approximately 1/2 its diameter. Select a screw extractor of the proper size and tap it into the stud or bolt. Turn the extractor counterclockwise to remove the stud or bolt.

Locating Metal Flaws and Cracks

Magnaflux and Zyglo are inspection techniques used to locate material flaws, such as stress cracks. Magnafluxing coats the part with fine magnetic particles and subjects the part to a magnetic field. Cracks cause breaks in the magnetic field,

Magnaflux indication of cracks

Helicoll installation

which are outlined by the particles. Since Magnaflux is a magnetic process, it is applicable only to ferrous materials. The Zyglo process coats the material with a fluorescent dye penetrant and then subjects it to blacklight inspection, under which cracks glow brightly. Parts made of any material may be tested using Zyglo. While Magnaflux and Zyglo are excellent for general inspection and locating hidden defects, specific checks of

suspected cracks may be made at lower cost and more readily using spot check dye. The dye is sprayed onto the suspected area, wiped off and the area is then sprayed with a developer. Cracks then will show up brightly. Spot check dyes will only indicate surface cracks; therefore, structural cracks below the surface may escape detection. When questionable, the part should be tested using Magnaflux, Zyglo or their equivalent.

REBUILDING GASOLINE ENGINES

The section is divided into two parts. The first, Cylinder Head Reconditioning, assumes that the cylinder head is removed from the engine, all manifolds are removed and the cylinder head is on a workbench. The camshaft should be removed from overhead cam cylinder heads. The second section, Cylinder Block Reconditioning, covers the block, pistons, connecting rods and crankshaft. It is assumed that the engine is mounted on a work stand and the cylinder head and all accessories are removed.

In many cases, a choice of methods is provided. The choice of method for a procedure is at the discretion of the user.

Many makes and types of special tools are available to the rebuilder for the express purpose of making a specific rebuilding operation easier and quicker. It is the choice of the rebuilder as to the tool desired and obtained.

Cylinder Head Reconditioning

IDENTIFY THE VALVES

Invert the cylinder head and clean the carbon from the valve heads. Number the valve heads from front to rear with touch-up paint or a felt tip marking pencil. Upon removal of the valves from the cylinder head, place them in a holder, made from cardboard, wood or metal, in their respective order.

REMOVE THE ROCKER ARMS

Remove the rocker arms and shaft or balls and nuts, if not done during the cylinder head removal. Wire the sets of rockers, balls and nuts together and identify according to the corresponding valve.

Individual rocker arm assembly

Rocker arm and shaft assembly—typical

Valve assembly using rotator on top of the valve spring

Cross section of valve assemblies with valve rotor cap on exhaust valve stem

REMOVE THE VALVES AND SPRINGS

Using an appropriate valve spring compressor, compress the valve springs and remove the keepers with needlenose pliers or a magnet. Release the compressor and remove the valve spring, retainer and oil seal from the valve stem. Remove the valve from the cylinder head and keep in order.

NOTE: Rotor units are used on numerous valve assemblies. Replace the rotor if any doubt exists on its performance.

DE-CARBON THE CYLINDER HEAD AND VALVES

Carbon is removed from the cylinder head combustion chamber, valves and valve ports by various methods. The most common is a wire brush tool, chucked to an electric drill. A hand held wire brush, a chisel made from hard wood or a special carbon removing tool supplied by a tool company is used to complete the carbon removal procedure.

CAUTION

When using a motorized wire brush, safety glasses must be worn to avoid personal injury.

CLEANING THE CYLINDER HEAD

The cylinder head and certain components can be cleaned of grease, corrosion and scale by immersing them in a "Hot Tank" solution. Generally, an automotive machine shop will have this type of equipment.

CAUTION

Consult with the "Hot Tank" operator to determine if overhead cam bearings of an OHC cylinder head will be damaged by the solution. If necessary to remove the bearings, replace them with new bearings.

CLEANING THE REMAINING CYLINDER HEAD PARTS

Using solvent, clean the rocker arm assemblies, (or rocker

Cross section of valve assemblies with roto-cap assembly under the spring

Removing carbon from the cylinder head

balls and nuts) springs, spring retainers, keepers, all bolts and nuts, push rods and rocker arm cover.

CHECK THE CYLINDER HEAD FOR WARPAGE

Place a straightedge across the gasket surface of the cylinder head. Using feeler gauges, determine the clearance at the cen-

Cleaning valve guides with wire type cleaner

Checking cylinder head surface for flatness with feeler gauge and straight edge

Location of straight edge to check cylinder head surface for flatness

ter of the straightedge. Measure across both diagonals, along the longitudinal centerline and across the cylinder head at several points. If warpage exceeds 0.003 in. in a 6 in. span, or 0.006 in. over the total length, the cylinder head must be resurfaced.

NOTE: If warpage exceeds the manufacturer's maximum tolerance for material removal, the cylinder head must be replaced.

When milling the cylinder heads of V-type engines, the intake manifold mounting position is altered and must be corrected by milling the manifold flange a proportionate amount.

CHECK THE VALVE STEM TO GUIDE CLEARANCE

Clean the valve stem with a solvent to remove all gum and varnish. Clean the valve guides with a solvent and/or a wire type expanding valve guide cleaner tool. Insert the proper valve into its guide and hold the valve head to the valve seat tightly. Mount a dial indicator on the spring side of the cylinder head so that the dial indicator foot is against the valve stem, protruding from the guide, at a 90° angle. Move the valve off its seat and measure the valve guide to stem clearance by moving the stem back and forth to actuate the dial indicator. Measure the

Measuring valve guide with small hole gauge

Measuring valve guide wear at valve stem

valve stems using a micrometer and compare to specifications to determine if the valve stem or valve guide is responsible for the excessive wear clearance.

An alternate method of checking the valve stem to guide clearance is to mount a dial indicator on the combustion side of the cylinder head, with the foot of the indicator to contact the side of the valve head. The valve head is moved away from its seat a predetermined distance, either by a special collar tool, placed on the valve stem between the head of the valve and the guide, or by measuring the height of the valve head above the seat with the use of a scale. The valve head is moved back and forth to actuate the dial indicator. Measure the valve stems, using a micrometer and compare to specifications.

Determination of wear from either the valve guide or valve stem can be made. Other types of measuring methods are available to the rebuilder. Go and No-Go gauge, inside caliper type small hole gauges or shim stock can be used to determine the wear of the guides.

Careful inspection will detect bellmouthing or elliptical wear of the guides, normally at the port end of the guide.

Measuring valve guide wear at valve stem

Effects of worn and bellmouthed guides on valve head seating

REPLACING VALVE SEAT INSERTS

Most exhaust and some intake valve seats are of the insert type and can be replaced if found to be loose, burned or cracked.

The valve seat insert can be removed by either pulling it from its counterbore with a puller, or by drilling a small hole into the seat insert on two sides and cracking it with a chisel. Care must be exercised to avoid drilling into the cylinder head. The insert counterbore in the cylinder head, should be machined prior to the insert installation, with special emphasis on having the bottom of the counterbore square to insure proper seating of the valve insert. Most inserts are supplied in standard, 0.015 in. and 0.030 in. oversizes.

After installation of the valve seat insert, grinding by a re-facing machine should be made to insure the seat is angled to specification and in proper relationship to the valve guide.

REPLACING VALVE GUIDES

INTEGRAL GUIDE TYPE

These types of cylinder heads do not have removable guides but

Correct seal installation and grinding in relation to the valve head

Machining cylinder head for valve seat insert installation

Cross section of valves showing exhaust valve seat insert and intake valve seat without insert. Method of measuring seat angle is illustrated

have the guide holes bored directly in the cylinder head material. When the clearances become excessive between the valve and guide, the guides can be reamed to an oversize dimension and oversize valves used. The "knurling" process may be used to recondition the inside of the guide surface, if the valve to guide clearance is not excessive.

A machining operation can be used to drill out the non-replaceable guide holes and have a standard type guide installed. This operation should be done by an automotive machine shop, equipped with the special boring machine.

REPLACEABLE GUIDE TYPE

Depending on the type of cylinder head, valve guides may be pressed, hammered, or shrunk in. In cases where the guides are shrunk into the head, replacement should be left to an equipped machine shop. In other cases, the guides are replaced as follows: Press or tap the valve guides out of the head using a stepped drift. Determine the height above the boss that the guide must extend and obtain a stack of washers, their I.D. similar to the guides O.D., of that height. Place the stack of washers on the guide and insert the guide into the boss.

NOTE: Valve guides are often tapered or beveled for installation.

Using the stepped installation tool, press or tap the guides into position. Ream the guides according to the size of the valve stem.

RESURFACING (GRINDING) THE VALVE FACE

Using a valve grinder, resurface the valves according to specifications.

Seat installation tool - typical

CAUTION

Valve face angle is not always identical to valve seat angle.

A minimum margin of $\frac{3}{64}$ in. should remain after grinding the valve. The valve stem tip should also be squared and resurfaced, by placing the stem in the V-block of the grinder and turning it while pressing lightly against the grinding wheel.

RESURFACING THE VALVE SEATS USING A GRINDER

Select a pilot of the correct size and a coarse stone of the correct seat angle. Lubricate the pilot if necessary and install the tool

Cross section of knurled valve guide

Valve guide removal tool

Valve guide installation tool with washer stack

Correct and incorrect grinding of the valve face with proper margin indicated

Centering and narrowing valve seat with correction stone

Grinding valve seats

Checking valve seat run-out with a dial gauge

in the valve guide. Move the stone on and off the seat at approximately two cycles per second, until all flaws are removed from the seat. Install a fine stone and finish the seat. Center and narrow the seat using correction stones. Intake seat width— $\frac{1}{16}$ – $\frac{5}{64}$ in. Exhaust seat width— $\frac{3}{64}$ – $\frac{1}{16}$ in.

CHECKING THE VALVE SEAT CONCENTRICITY

1. Coat the valve face with Prussian blue dye, install the valve and rotate it on the valve seat. If the entire seat becomes coated and the valve is known to be concentric, the set is concentric.

2. Install a dial gauge pilot into the guide and rest the arm on the valve seat. Zero the gauge and rotate the arm around the seat. Runout should not exceed 0.002 in.

LAPPING THE VALVES

NOTE: Valve lapping is done to ensure efficient sealing of resurfaced valves and seats. Valve lapping alone is not recommended for use as a resurface procedure.

1. Invert the cylinder head, lightly lubricate the valve stems and install the valves in the head as numbered. Coat valve seats with fine grinding compound and attach the lapping tool suction cup to a valve head.

NOTE: Moisten the suction cup.

2. Rotate the tool between the palms, changing position and lifting the tool often to prevent grooving. Lap the valve until a smooth polished seat is evident. Remove the valve and tool and rinse away all traces of grinding compound.

3. Fasten a suction cup to a piece of drill rod and mount the rod in a hand drill. Proceed as above, using the hand drill as a lapping tool.

CAUTION

Due to the higher speeds involved when using the hand drill, care must be exercised to avoid grooving the seat.

4. Lift the tool and change direction of rotation often.

NOTE: Many manufacturers do not recommend the lapping of valves to the seats after each has been re-ground. However, for the rebuilder to be certain a perfect

Hand lapping the valve to the seat

seal exists between the valve and the seat, lapping is suggested.

CHECK THE VALVE SPRINGS

Test the spring pressure at the installed and compressed (installed height minus valve lift) height using a valve spring tester. Springs used on small displacement engines (up to 3 liters) should be ± 1 lb. of all other springs in either position. A tolerance of ± 5 lbs. is permissible on larger engines.

INSTALL VALVE STEM SEALS

Due to the pressure differential that exists at the ends of the intake valve guides (atmospheric pressure above, manifold vacuum below), oil is drawn through the valve guides into the intake port. This has been alleviated somewhat since the addition of positive crankcase ventilation, which lowers the pressure above the guides. Several types of valve stem seals are available to reduce blow-by. Certain seals simply slip over the stem and guide boss, while others require that the boss be machined. Recently, Teflon guide seals have become popular. Consult a parts supplier or machinist concerning availability and suggested usages.

NOTE: When installing seals, ensure that a small amount of oil is able to pass the seal to lubricate the valve guides; otherwise, excessive wear may result.

INSTALL THE VALVES

Lubricate the valve stems and install the valves in the cylinder head as numbered. Lubricate and position the seals (if used, see above) and the valve springs. Install the spring retainers, compress the springs and insert the keys using needlenose pliers or a tool designed for this purpose.

NOTE: Retain the keys with wheel bearing grease during installation.

CHECK VALVE SPRING INSTALLED HEIGHT

Measure the distance between the spring pad and the lower edge of the spring retainer and compare to specifications. If the installed height is incorrect, add shim washers between the spring pad and the spring.

CAUTION

Use only washers designed for this purpose.

Mechanical valve lapping tool

Testing valve spring compressed height

Measuring valve spring assembled height with caliper

Oil seal installation on exhaust and intake valves, using "umbrella" and O-ring type seals

Installing intake valve oil seals, Perfect Circle type, using plastic sleeve and special installation tool

INSPECT THE ROCKER ARMS, BALLS, STUDS and NUTS

Visually inspect the rocker arms, balls, studs and nuts for cracks, galling, burning, scoring, or wear. If all parts are intact, liberally lubricate the rocker arms and balls and install them on the cylinder head. If wear is noted on the rocker arm at the point of valve contact, grind it smooth and square, removing as little material as possible. Replace the rocker arm if excessively worn. If a rocker stud shows signs of wear, it must be replaced. If a rocker nut shows stress cracks, replace it.

INSPECT THE ROCKER SHAFT(S) AND ROCKER ARMS

Remove rocker arms, springs and washers from rocker shaft.

NOTE: Lay out parts in the order in which they are removed.

Inspect rocker arms for pitting or wear on the valve contact point, or excessive bushing wear. Bushings need only be replaced if wear is excessive, because the rocker arm normally contacts the shaft at one point only. Grind the valve contact

Stress cracks in rocker arm nut

Checking rocker arm shaft O.D. with mi-crometer

Checking rocker arms

Reaming the stud bore for oversize rocker studs

Checking for bent push rod

Exploded view of hydraulic lifter—typical

point of rocker arm smooth if necessary, removing as little material as possible. If excessive material must be removed to smooth and square the arm, it should be replaced. Clean out all oil holes and passages in rocker shaft. If shaft is grooved or worn, replace it. Lubricate and assemble the rocker shaft.

REPLACING ROCKER STUDS

In order to remove a threaded stud, lock two nuts on the stud and unscrew the stud using the lower nut. Coat the lower threads of the new stud with Loctite and install.

Two alternative methods are available for replacing pressed in studs. Remove the damaged stud using a stack of washers and a nut or use a stud puller. In the first, the boss is reamed 0.005–0.006 in. oversize and an oversize stud pressed in. Control the stud extension over the boss using washers, in the same manner as valve guides. Before installing the stud, coat it with white lead and grease. To retain the stud more positively, drill a hole through the stud and boss and install a roll pin. In the second method, the boss is tapped and a threaded stud installed. Retain the stud using a locking compound.

INSPECT THE PUSHRODS

Remove the pushrods and if hollow, clean out the oil passages using fine wire. Roll each pushrod over a piece of clean glass. If a distinct clicking sound is heard as the pushrod rolls, the rod is bent and must be replaced.

The length of all pushrods must be equal. Measure the length of the pushrods, compare to specifications and replace as necessary.

INSPECT THE VALVE LIFTERS

MECHANICAL OR HYDRAULIC

Remove lifters from their bores and remove gum and varnish, using solvent. Clean walls of lifter bores. Check lifters for concave wear as illustrated. If face is worn concave, replace lifter and carefully inspect the camshaft. Lightly lubricate lifter and insert it into its bore. If play is excessive, an oversize lifter must be installed (where possible). Consult a machinist concerning feasibility. If play is satisfactory, remove, lubricate and reinstall the lifter.

Removing a pressed in rocker stud

Wear patterns on base of lifter bodies

Checking the tappet for concave wear on its base, using second tappet for a straight edge

TESTING HYDRAULIC LIFTER LEAK DOWN RATE

Special testers are available for the checking of the hydraulic lifter leak down rate. Special instructions accompanying the testers should be followed by the rebuilder. If the tester is not available, the following alternate method can be used.

Submerge lifter in a container of kerosene. Chuck a used pushrod or its equivalent into a drill press. Position container

Hydraulic lifter leakdown tester—typical

of kerosene so pushrod acts on the lifter plunger. Pump lifter with the drill press, until resistance increases. Pump several more times to bleed any air out of lifter. Apply very firm, constant pressure to the lifter and observe rate at which fluid bleeds out of lifter. If the fluid bleeds very quickly (less than 15 seconds), lifter is defective. If the time exceeds 60 seconds, lifter is sticking. In either case, recondition or replace lifter. If lifter is operating properly (leak down time 15–60 seconds) lubricate and reinstall.

ENGINE BLOCK RECONDITIONING

MARKING MAIN AND CONNECTING ROD CAPS

Using a punch, mark the corresponding main bearing caps and saddles according to position (i.e., one punch on the front main cap and saddle, two on the second, three on the third, etc.). Using number stamps, identify the corresponding connecting rods and caps, according to cylinder (if no numbers are present). Remove the main and connecting rod caps and place sleeves of plastic tubing over the connecting rod bolts, to protect the journals as the crankshaft is removed.

REMOVE THE RIDGE

In order to facilitate removal of the piston and connecting rod, the ridge at the top of the cylinder (unworn area; see illustration) must be removed. Place the piston at the bottom of the bore and cover it with a rag. Cut the ridge away using a ridge reamer, exercising extreme care to avoid cutting too deeply. Remove the rag and remove cuttings that remain at the piston.

CAUTION

If the ridge is not removed and new rings are installed, damage to rings will result.

REMOVING THE PISTON AND CONNECTING ROD

Invert the engine and push the pistons and connecting rods out of the cylinders. If necessary, tap the connecting rod boss with a wooden hammer handle, to force the piston out.

Connecting rod matched to cylinder with a number stamp

Scribe connecting rod matchmarks

Cylinder bore ridge

Removing the piston and connecting rod assembly

CAUTION

Do not attempt to force the piston past the uncut cylinder ridge.

REMOVE THE OIL GALLERY PLUGS

Threaded plugs should be removed using an appropriate (usually square) wrench. To remove soft, pressed in plugs, drill a hole in the plug and thread in a sheet metal screw. Pull the plug out by the screw using pliers.

REMOVING FREEZE PLUGS

Drill a hole in the center of the freeze plugs and pry them out using a drift or special puller.

CHECK THE BORE DIAMETER AND SURFACE

Visually inspect the cylinder bores for roughness, scoring, or scuffing. If evident, the cylinder bore must be bored or honed oversize to eliminate imperfections and the smallest possible oversize piston used. The new pistons should be given to the machinist with the block, so that the cylinders can be bored or honed exactly to the piston size (plus clearance). If no flaws are evident, measure the bore diameter using a telescope gauge and micrometer, or dial gauge, parallel and perpendicular to the engine centerline, at the top (below the ridge) and bottom of the bore. Subtract the bottom measurements from the top to determine taper and the parallel to the centerline measurements from the perpendicular measurements to determine eccentricity. If the measurements are not within specifications, the cylinder must be bored or honed and an oversize piston installed. If the measurements are within specifications the cylinder may be used as is, with only finish honing.

CYLINDER SLEEVE LINERS

DRY CYLINDER LINERS

Various engines are fitted with dry type cylinder liners at the

Location of oil gallery plugs, core plugs and camshaft bearing bore plug – V8 engine (some engines may be equipped with a balance shaft)

Location of oil gallery and water jacket plugs – 6 cylinder engine typical

Measuring telescope gauge to determine bore size

time of manufacture. This type of liner can be replaced with the use of special pulling tools at the time of engine overhaul.

When the cylinder bore is part of the block assembly and if only one or two cylinder bores are damaged, sleeves can be installed in the damaged bores to avoid reboring all cylinders to an oversize condition.

The services of a competent automotive machine shop should be used for the boring of the cylinders and the installation of the liners.

WET CYLINDER LINERS

Removable cylinder liners are used in varied engines that can be lifted from the engine block without the use of pullers or of a press. Soft metal rings are used at the base of the liners to seal between machined surfaces on the engine block and the cylinder liner, to prevent coolant from entering the engine lubricating system.

The cylinder head gasket is used to seal the top of the cylinder liner and the cylinder head. Should the cylinder head be re-

Wet cylinder liner—typical

Checking points for cylinder bore out-of-round measurement. Out-of-round is difference between measurement A and B

Checking cylinder bore taper and out-of-round with a dial indicator cylinder bore gauge

Measuring cylinder bore with telescope

moved or the engine overhauled, a projection of approximately 0.002–0.006 in. (depending upon engine manufacturer's specifications) should exist at the liner top, above the surface of the engine block. If the projection is not present, new sealing rings should be installed at the bottom of the cylinder liners to prevent coolant leakage or compression loss.

Installation of pistons, rings and liners are installed as sets to control the weight and balance of the components.

CHECK THE CYLINDER BLOCK BEARING ALIGNMENT

Remove the upper bearing inserts. Place a straightedge in the bearing saddles along the centerline of the crankshaft. If clear-

Checking points for cylinder bore taper measurement. Taper is difference between measurement A and B

Checking main bearing saddle alignment

Measuring cylinder gauge to determine bore size

ance exists between the straightedge and the center saddle, the block must be linebored.

HOT-TANK THE BLOCK

Have the block hot-tanked to remove grease, corrosion and scale from the water jackets.

NOTE: Consult the operator to determine whether the camshaft bearings will be damaged during the hot-tank process.

SERVICE THE CRANKSHAFT

Ensure that all oil holes and passages in the crankshaft are open and free of sludge. If necessary, have the crankshaft ground to the largest possible undersize.

Have the crankshaft magnafluxed, to locate stress cracks. Consult a machinist concerning additional service procedures, such as surface hardening (e.g., Nitriding, Tuftriding) to improve wear characteristics, cross drilling and chamfering the oil holes to improve lubrication and balancing.

Measure the main bearing journals at each end twice (90° apart) using a micrometer, to determine diameter, journal taper and eccentricity. If journals are within tolerances, reinstall bearing caps at their specified torque. Using a telescope gauge and micrometer, measure bearing I.D. parallel to piston axis and at 30° on each side of piston axis. Subtract journal O.D. from bearing I.D. to determine oil clearance. If crankshaft journals appear defective, or do not meet tolerances, there is no need to measure bearings; for the crankshaft will require grinding and/or-undersize bearings will be required. If bearing appears defective, cause for failure should be determined prior to replacement.

Refer to the failure diagnosis section to help you determine the cause of the failure.

CHECK THE BLOCK FOR CRACKS

Visually inspect the block for cracks or chips. The most common locations are as follows:

1. Adjacent to freeze plugs
2. Between the cylinders and water jackets
3. Adjacent to the main bearing saddles
4. At the entrance bottom of the cylinders

Check only suspected cracks using spot check dye (see introduction). If a crack is located, consult a machinist concerning possible repairs.

Magnaflux the block to locate hidden cracks. If cracks are located, consult a machinist about feasibility of repair.

NOTE: Engine blocks that are porous or have sand holes, can be repaired with metallic plastic where coolant or oil pressure does not exist. Do not attempt to repair cracked blocks with the metallic plastic.

CHECK THE BLOCK DECK FOR WARPAGE

Using a straightedge and feeler gauges, check the block deck for warpage in the same manner that the cylinder head is checked (see Cylinder Head Reconditioning). If warpage exceeds specifications, have the deck resurfaced.

NOTE: In certain cases a specification for total material removal (Cylinder head and block deck) is provided. This specification must not be exceeded.

CHECK THE DECK HEIGHT

The deck height is the distance from the crankshaft centerline to the block deck. To measure, invert the engine and install the crankshaft, retaining it with the center main cap. Measure the

distance from the crankshaft journal to the block deck, parallel to the cylinder centerline. Measure the diameter of the end (front and rear) main journals, parallel to the centerline of the cylinders, divide the diameter in half and subtract it from the previous measurement. The results of the front and rear measurements should be identical. If the difference exceeds 0.005 in., the deck height should be corrected.

NOTE: Block deck height and warpage should be corrected together.

INSTALL THE OIL GALLERY PLUGS AND FREEZE PLUGS

Coat freeze plugs with sealer and tap into position using a piece of pipe, slightly smaller than the plug, as a driver. To ensure retention, stake the edges of the plugs. Coat threaded oil

Installation of cup type and expansion type core plugs with special tool

gallery plugs with sealer and install. Drive replacement soft plugs into block using a large drift as a driver. Rather than reinstalling lead plugs, drill and tap the holes and install threaded plugs, where possible.

CLEAN AND INSPECT THE CAMSHAFT

Degrease the camshaft, using solvent and clean out all oil holes. Visually inspect cam lobes and bearing journals for excessive wear. If a lobe is questionable, check all lobes as indicated below. If a journal or lobe is worn, the camshaft must be reground or replaced.

NOTE: If a journal is worn, there is a good chance that the bushings are worn.

If lobes and journals appear intact, place the front and rear journals in V-blocks and rest a dial indicator on the center journal. Rotate the camshaft to check straightness. If deviation exceeds 0.001 in., replace the camshaft.

Check the camshaft lobes with a micrometer, by measuring the lobes from the nose to base and again at 90°. The lift is determined by subtracting the second measurement from the first. If all exhaust lobes and all intake lobes are not identical with specs, the camshaft must be reground or replaced.

REPLACE THE CAMSHAFT BEARINGS

If excessive wear is indicated or if the engine is being completely rebuilt, camshaft bearings should be replaced as follows: Drive the camshaft rear plug from the block. Assemble the removal puller with its shoulder on the bearing to be removed. Gradually tighten the puller nut until bearing is removed. Remove remaining bearings, leaving the front and rear for last.

Chain driven camshaft assembly—typical

To remove front and rear bearings, reverse position of the tool, so as to pull the bearings in toward the center of the block. Leave the tool in this position, pilot the new front and rear bearings on the installer and pull them into position. Return the tool to its original position and pull remaining bearings into position.

NOTE: Ensure that oil holes align when installing bearings.

Replace camshaft rear plug and stake it into position to aid retention.

INSTALL THE CAMSHAFT

Liberalily lubricate the camshaft lobes and journals and slide the camshaft into the block.

CAUTION

Exercise extreme care to avoid damaging the bearings when inserting the camshaft.

Be careful not to force the shaft towards the rear of the engine block as this can unseat the welch plugs in some engines. Install and tighten the camshaft thrust plate retaining bolts.

CHECK CAMSHAFT END-PLAY

1. Using feeler gauges, determine whether the clearance between the camshaft boss (or gear) and backing plate is within specifications. Install shims behind the thrust plate, or reposition the camshaft gear and retest end-play.

2. Mount a dial indicator stand so that the stem of the dial indicator rests on the nose of the camshaft, parallel to the camshaft axis. Push the camshaft as far in as possible and zero the gauge. Move the camshaft outward to determine the amount of camshaft end-play. If the end-play is not within tolerance, install shims behind the thrust plate or reposition the camshaft gear and retest.

INSTALLING BEARING INSERTS IN BLOCK OR CONNECTING ROD BORES

The bearing inserts must fit tightly in the connecting rod or main bearing bores. The bearing inserts are made slightly larger than the actual diameter of the bore into which they are to be used. As the bearing caps are drawn tight, the bearing inserts are compressed, assuring a positive contact between the bearing insert and the bore. This is necessary to relieve the heat and to give the bearing insert a firm support for the loads place don them during engine operation. This increased diameter of the bearing insert is referred to as bearing "crush". Because of this, the bearing caps, connecting rods and engine block must not be filed, lapped or reworked in any manner and all attaching bolts must be properly torqued.

Main and connecting rod bearing inserts are made with the width across the open end slightly larger than the main bearing or connecting rod bearing bore, so that the bearing inserts must be snapped or lightly forced into its seat. A spread of 0.025 in. is normally minimum on most engines, but will vary from engine to engine. (Some bearing kits will have instructions for the proper installation of the inserts.)

To adjust the bearing spread of the thick wall bearings, such

Checking camshaft end-play with dial indicator

1. PUSH CAM TO REAR OF ENGINE
2. SET DIAL ON ZERO
3. PULL CAM FORWARD AND RELEASE

as main bearing inserts, place one end of the bearing insert on a wood block and strike the other end with a soft mallet to decrease the spread. To increase the spread, place the bearing insert ends on a wood block and strike the back of the insert with a soft mallet, squarely and lightly. The bearing spread on the thin walled bearing inserts, such as connecting rod bearing inserts, can be adjusted by hand, either spreading with the thumbs and forefingers of both hands, or by squeezing the bearing insert by the palm of the hand to decrease the spread. Check the spread distance often during the adjustment procedure.

INSTALL THE REAR MAIN SEAL

Position the block with the bearing saddles facing upward. Lay the rear main seal in its groove and press it lightly into its seat. Place a piece of pipe the same diameter as the crankshaft journal into the saddle and firmly seat the seal. Hold the pipe in position and trim the ends of the seal flush if required.

INSTALL THE CRANKSHAFT

Thoroughly clean the main bearing saddles and caps. Place the upper halves of the bearing inserts on the saddles and press into position.

NOTE: Ensure that the oil holes align.

Press the corresponding bearing inserts into the main bearing caps. Lubricate the upper main bearings and lay the crank-

shaft in position. Place a strip of Plastigage on each of the crankshaft journals, install the main caps and torque to specifications. Remove the main caps and compare the Plastigage to the scale on the Plastigage envelope. If clearances are within tolerances, remove the Plastigage, turn the crankshaft 90°, wipe off all oil and retest. If all clearances are correct, remove all Plastigage, thoroughly lubricate the main caps and bearing journals and install the main caps.

If clearances are not within tolerance, the upper bearing inserts may be removed, without removing the crankshaft, using a bearing roll out pin. Roll in a bearing that will provide proper clearance and retest. Torque all main caps, excluding the thrust bearing cap, to specifications. Tighten the thrust bearing cap finger tight. To properly align the thrust bearing, pry the crankshaft the extent of its axial travel several times, the last movement held toward the front of the engine and torque the thrust bearing cap to specifications. Determine the crankshaft end-play and bring within tolerance with thrust washers.

MEASURE CRANKSHAFT END-PLAY

Mount a dial indicator stand on the block, with the dial indicator stem resting on the crankshaft parallel to the crankshaft axis. Pry the crankshaft rearward to the full extent of its travel and zero the indicator. Pry the crankshaft forward and record crankshaft end-play.

NOTE: Crankshaft end-play also may be measured at the thrust bearing, using feeler gauges.

CLEAN AND INSPECT THE PISTONS AND CONNECTING RODS

Using a ring expander, remove the rings from the piston. Remove the retaining rings (if so equipped) and remove piston pin.

CAUTION

If the piston pin must be pressed out, determine the proper method and use the proper tools; otherwise the piston will distort.

Clean the ring grooves using an appropriate tool, exercising care to avoid cutting too deeply. Thoroughly clean all carbon and varnish from the piston with solvent.

CAUTION

Do not use a wire brush or caustic solvent on pistons.

Inspect the pistons for scuffing, scoring, cracks, pitting, or excessive ring groove wear. If wear is evident, the piston must be replaced. Check the connecting rod length by measuring the rod from the inside of the large end to the inside of the small end using calipers. All connecting rods should be equal length. Replace any rod that differs from the others in the engine. Have the connecting rod alignment checked in an alignment fixture by a machinist. Replace any twisted or bent rods.

Magnaflux the connecting rods to locate stress cracks. If cracks are found, replace the connecting rod.

FINISH HONE THE CYLINDERS

Chuck a flexible drive hone into a power drill and insert it into the cylinder. Start the hone and move it up and down in the cylinder at a rate which will produce approximately a 60° cross-hatch pattern.

NOTE: Do not extend the hone below the cylinder bore.

After developing the pattern, remove the hone and recheck piston fit. Wash the cylinders with a detergent and water solution to remove abrasive dust, dry and wipe several times with a rag soaked in engine oil.

CHECK PISTON RING END-GAP

Compress the piston to be used in a cylinder, one at a time, into that cylinder and press them approximately 1 in. below the deck with an inverted piston. Using feeler gauges, measure the ring end-gap and compare to specifications. Pull the ring out of the cylinder and file the ends with a fine file to obtain proper clearance.

CAUTION

If inadequate ring end-gap exists, ring breakage could result.

Cross hatching of cylinder bore by finish honing

Checking ring gap in cylinder bore

FIT THE PISTONS TO THE CYLINDERS

Using a telescope gauge and micrometer, or a dial gauge, measure the cylinder bore diameter perpendicular to the piston pin, 2 1/2 in. below the deck. Measure the piston perpendicular to its pin on the skirt. The difference between the two measurements is the piston clearance. If the clearance is within specifications or slightly below (after boring or honing), finish honing is all that is required. If the clearance is excessive, try to obtain a slightly larger piston to bring clearance within specifications. Where this is not possible, obtain the first oversize piston and hone (or if necessary, bore) the cylinder to size.

ASSEMBLE THE PISTONS AND CONNECTING RODS

Inspect piston pin, connecting rod, small end bushing and piston bore for galling, scoring or excessive wear. If evident, replace defective part(s). Measure the I.D. of the piston boss and connecting rod small end and the O.D. of the piston pin. If within specifications, assemble piston pin and rod.

CAUTION

CAUTION: If piston pin must be pressed in, determine the proper method and use the proper tools; otherwise the piston will distort.

Install the lock rings; ensure that they seat properly. If the parts are not within specifications, determine the service method for the type of engine. In some cases, piston and pin are serviced as an assembly when either is defective. Others specify reaming the piston and connecting rods for an oversize pin. If the connecting rod bushing is worn, it may in many cases be replaced. Reaming the piston and replacing the rod bushing are machine shop operations.

INSTALL THE PISTON RINGS

Inspect the ring grooves in the piston for excessive wear or taper. If necessary, recut the groove(s) for use with an overwidth ring or a standard ring and spacer. If the groove is worn uniformly, overwidth rings or standard rings and spacers may be installed without recutting. Roll the outside of the ring around the groove to check for burrs or deposits. If any are found, remove with a fine file. Hold the ring in the groove and measure side clearance. If necessary, correct as indicated above.

NOTE: Always install any additional spacers above the piston ring.

The ring grooves must be deep enough to allow the ring to seat below the lands. In many cases, a "go-no-go" depth gauge will be provided with the piston rings. Shallow grooves may be corrected by recutting, while deep grooves require some type of filler or expander behind the piston. Consult the piston ring supplier concerning the suggested method. Install the rings on the piston, lowest ring first, using a ring expander.

NOTE: Position the ring markings as specified by the manufacturer.

INSTALL THE PISTONS

Press the upper connecting rod bearing halves into the connecting rods and the lower halves into the connecting rod caps. Position the piston ring gaps according to specifications and lubricate the pistons. Install a ring compressor on the piston and press two long (8 in.) pieces of plastic tubing over the rod bolts. Using the plastic tubes as a guide, press the piston into the bore and onto the crankshaft with a wooden hammer handle. After seating the rod on the crankshaft journal, remove the tubes and install the cap nuts finger tight. Install the remain-

Tubing used as a guide during piston-connecting rod installation

ing pistons in the same manner. Invert the engine and check the bearing clearance at two points (90° apart) on each journal with Plastigage.

NOTE: Do not turn the crankshaft with Plastigage installed.

If clearance is within tolerances, remove all Plastigage, thoroughly lubricate the journals and torque the rod caps to specifications. If clearance is not within specifications, install different thickness bearing inserts and recheck.

CAUTION

Never shim or file the connecting rods or caps.

Always install plastic tube sleeves over the rod bolts when the caps are not installed, to protect the crankshaft journals.

CHECK CONNECTING ROD SIDE CLEARANCE

Determine the clearance between the sides of the connecting rods and the crankshaft, using feeler gauges. If clearance is below the minimum tolerance, the rod may be machined to pro-

Using torque wrench to measure timing chain deflection

vide adequate clearance. If clearance is excessive, substitute an unworn rod and recheck. If clearance is still outside specifications, the crankshaft must be welded and reground, or replaced.

INSPECT THE TIMING CHAIN

Visually inspect the timing chain for broken or loose links and replace the chain if any are found. If the chain will flex sideways, it must be replaced.

NOTE: If the original timing chain is to be reused, install it in its original position.

INSPECT THE TIMING CHAIN DEFLECTION

Different methods are used by the engine manufacturers to measure the timing chain deflection and to determine the condition of the chain. Three such methods are as follows:

1. Rotate the crankshaft in a counterclockwise direction to remove the slack on the left side of the chain. Make a reference mark on the block and measure from the mark to the outside of the chain, halfway between the camshaft and crankshaft sprockets. Rotate the crankshaft in the opposite direction and remove the slack from the right side of the chain. Force the chain outward on the left side and measure from the original reference mark to the chain. The difference between the first and second measurements is the amount of chain deflection. The allowable deflection can be from $\frac{1}{4}$ – $\frac{1}{2}$ in., depending upon the manufacturer.

2. The second method of chain deflection measurement is to block the crankshaft to prevent movement. Using a torque wrench and socket on the camshaft sprocket bolt and placing a scale even with the edge of a chain link, apply 30 ft. lbs. (w/cylinder head on block) or 15 ft. lbs. (w/cylinder head off block) in the direction of engine rotation and obtain a reference point on the scale to link. Apply 30 ft. lbs. (w/cylinder head on block) or 15 ft. lbs. (w/cylinder head off block) in the opposite direction and measure the chain movement on the scale. The measurement should not exceed $\frac{1}{8}$ in.

3. A third method of measuring timing chain deflection is to rotate the crankshaft clockwise until the No. 1 piston is on its firing stroke at TDC. The damper timing mark should point to TDC on the timing degree indicator. Remove the valve cover to expose the rocker arms of the companion or opposite cylinder to the No. 1 piston. Install a dial indicator on the push rod or rocker arm of the exhaust valve of this opposite or companion cylinder in a manner to register the push rod or rocker arm upward movement. Zero the dial indicator and slowly turn the crankshaft counterclockwise until the slightest movement is recorded on the dial indicator. Stop and observe the damper timing mark for the number of degrees of travel from TDC. If the reading on the timing degree indicator exceeds 6–8 degrees, replace the timing chain and sprockets.

OVERHEAD CAM TIMING CHAINS

Timing chains for the overhead cam engines are difficult to examine for looseness due to the chain tensioners used to maintain a controlled tension on the chain while in use. The chains are usually checked off the engine by measurement of a predetermined number of links with the chain stretched tight. Should the measurement of the links exceed the manufacturer's specifications, the chain should be replaced.

Another method is to wrap the chain around the sprockets and measure each chain/sprocket diameter. Should the manufacturer's specifications be exceeded, the chain and sprocket should be replaced. Where no specifications exist, the repairperson must make a professional determination to either replace the chain and sprockets or not.

Checking connecting rod end clearance with feeler gauge blade

Checking timing chain deflection using point on engine blocks as reference point

Checking timing chain deflection with timing indicator scale

Example of timing chain/sprocket measurement

TIMING BELT INSPECTION

The timing belt should be inspected for hardness, separation of plies, cracks, worn or missing teeth and abnormal side wear. If the timing belt is removed for any reason, a new belt must be installed. Do not re-use the old belt.

CHECK TIMING GEAR BACKLASH AND RUNOUT

Mount a dial indicator with its stem resting on a tooth of the camshaft gear. Rotate the gear until all slack is removed and zero the indicator. Rotate the gear in the opposite direction until slack is removed and record gear backlash. Mount the indicator with its stem resting on the edge of the camshaft gear, parallel to the axis of the camshaft. Zero the indicator and turn the camshaft gear one full turn, recording the runout. If either backlash or runout exceed specifications, replace the worn gear(s).

OIL PUMP

Three major types of oil pumps are used, positive gear type (with or without crescent), rotor type and the trochoid type. Regardless of the type pump used, a determination must be made, by measurements and examination, in regards to the re-use, overhaul or replacement of the oil pump assembly.

NOTE: It is recommended to replace the oil pump assembly with a new unit when a major engine overhaul is done.

Inspection

The oil pump and its components must be inspected for any of the following conditions.

1. Worn, pitted or damaged gear teeth surfaces.
2. Abnormal gear side wear, scores or burrs.
3. Oil pump body and gear pockets for abnormal wear, scores, burrs, grooves or nicks.
4. Correct measurement of internal components and body to manufacturer's specifications.
5. Pressure regulator valve for wear, scores, nicks or burrs.
6. Pressure regulator spring for distortion, breakage, correct length and tension.

Priming the Oil Pump

Before the engine start-up, the oil pump must be primed. Manufacturers vary in their recommendations with either engine oil or petroleum jelly used as the priming agent. Whenever possible, follow the manufacturer's recommended priming procedure.

Completing the Rebuilding Process

Following the above procedures, complete the rebuilding process as follows:

Fill the oil pump with oil, or petroleum jelly, to prevent cavitating (sucking air) on initial engine start up. Install the oil pump and the pickup tube on the engine. Coat the oil pan gasket as necessary and install the gasket and the oil pan. Mount the flywheel and the crankshaft vibrational damper or pulley on the crankshaft.

NOTE: Always use new bolts when installing the flywheel.

Inspect the clutch shaft pilot bushing in the crankshaft. If the bushing is excessively worn, remove it with an expanding puller and a slide hammer and tap a new bushing into place.

Position the engine, cylinder head side up. Lubricate the lifters and install them into their bores. Install the cylinder head and torque it as specified in the car section. Insert the pushrods (where applicable) and install the rocker shaft(s) (if so equipped) or position the rocker arms on the pushrods. If solid lifters are utilized, adjust the valves to the "cold" specifications.

Mount the intake and exhaust manifolds, the carburetor(s), the distributor and spark plugs. Adjust the point gap and the static ignition timing. Mount all accessories and install the engine in the car. Fill the radiator with coolant and the crankcase with high quality engine oil.

BREAK-IN PROCEDURE

Before starting the engine, be sure all coolant hoses are attached and tight, the coolant level is correct, a new oil filter is installed and the crankcase filled with the proper level of oil.

The oil pump should be primed and if possible, the engine lubrication system should be charged with a pressure tank. Adjust the tappets (if required), the timing and carburetor as accurately as possible.

Start the engine and adjust the throttle to an approximate engine speed of 1000 to 2000 rpm, until the engine reaches normal operating temperature, normally within 20-30 minutes.

CAUTION

Do not leave the vehicle unattended during the warm-up period. Observe the engine operation and check for any oil or coolant leaks. Stop the engine immediately if a problem exists, to avoid engine damage.

After the engine has "run-in", lower the idle speed and stop the engine. Retorque the cylinder head bolts as required.

NOTE: Engines with aluminum heads or blocks must be allowed to cool to room temperature before any bolts are retorqued.

After rechecking the coolant and oil levels, make any further adjustments as necessary.

Follow the manufacturer's recommended driving break-in procedure or as a general rule, the following procedures may be used.

Drive the vehicle on the highway and accelerate from 30-50 mph, approximately 10-15 times, traffic flow permitting, to properly seat the piston rings to the cylinder walls. If traffic flow does not permit this procedure, accelerate the engine rapidly during shifting through the intermediate gears. The vehicle should be put in light duty service for the first 50 miles and sustained high speed should be avoided during the first 100 miles. Most important: Do not lug the engine. (Lugging exists when the engine does not respond to further opening of the throttle.)

Engine Rebuilding

Import Trucks

This section describes, in detail, the procedures involved in rebuilding a typical engine. The procedures are basically identical to those used in rebuilding engines of nearly all design and configurations.

The section is divided into two parts. The first, Cylinder Head Reconditioning, assumes that the cylinder head is removed from the engine, all manifolds are removed, and the cylinder head is on a workbench. The camshaft should be removed from overhead cam cylinder heads. The second section, Cylinder Block Reconditioning, covers the block, pistons, connecting rods and crankshaft. It is assumed that the engine is mounted on a work stand, and the cylinder head and all accessories are removed.

Procedures are identified as follows:

Unmarked—Basic procedures that must be performed in order to successfully complete the rebuilding process.

Starred (*)—Procedures that should be performed to ensure maximum performance and engine life.

Double starred ()**—Procedures that may be performed to increase engine performance and reliability.

In many cases, a choice of methods is also provided. Methods are identified in the same manner as procedures. The choice of method for a procedure is at the discretion of the user.

The tools required for the basic rebuilding procedure should, with minor exceptions, be those included in a mechanic's tool kit. An accurate torque wrench, and a dial indicator (reading in thousandths) mounted on a universal base should be available. Special tools, where required, all are readily available from the major tool suppliers. The services of a competent automotive machine shop must also be readily available.

When assembling the engine, any parts that will be in frictional contact must be pre-lubricated, to provide protection on initial start-up. Any product specifically formulated for this purpose may be used. **NOTE:** Do not use engine oil. Where semi-permanent (locked but removable) installation of bolts or nuts is desired, threads should be cleaned and coated with Loctite® or a similar product (non-hardening).

Aluminum has become increasingly popular for use in engines, due to its low weight and excellent heat transfer characteristics. The following precautions must be observed when handling aluminum engine parts:

—Never hot-tank aluminum parts.

—Remove all aluminum parts (identification tags, etc.) from engine parts before hot-tanking (otherwise they will be removed during the process).

—Always coat threads lightly with engine oil or anti-seize compounds before installation, to prevent seizure.

—Never over-torque bolts or spark plugs in aluminum threads. Should stripping occur, threads can be restored using any of a number of thread repair kits available (see next section).

Magnaflux and Zyflo are inspection techniques used to locate material flaws, such as stress cracks. Magnafluxing coats the part with fine magnetic particles, and subjects the part to a magnetic field. Cracks cause breaks in the magnetic field, which are outlined by the particles. Since Magnaflux is a magnetic process, it is applicable only to ferrous materials. The Zyflo process coats the material with a fluorescent dye penetrant, and then subjects it to blacklight inspection, under which cracks glow brightly. Parts made of any material may be tested using Zyflo. While Magnaflux and Zyflo are excellent for general inspection, and locating hidden defects, specific checks of suspected cracks may be made at lower cost and more readily using spot check dye. The dye is sprayed onto the suspected area, wiped off, and the area is then sprayed with a developer. Cracks then will show up brightly. Spot check dyes will only indicate surface cracks; therefore, structural cracks below the surface may escape detection. When questionable, the part should be tested using Magnaflux or Zyflo.

REPAIRING DAMAGED THREADS

Several methods of repairing damaged threads are available. Heli-Coil® (shown here), Keenserts® and Microdot® are among the most widely used. All involve basically

the same principle—drilling out stripped threads, tapping the hole and installing a pre-wound insert—making welding, plugging and oversize fasteners unnecessary.

Two types of thread repair inserts are usually supplied—a standard type for most Inch Coarse, Inch Fine, Metric Coarse and Metric Fine thread sizes and a spark plug type to fit most spark plug port sizes. Consult the individual manufacturer's catalog to determine exact applications. Typical thread repair kits will contain a selection of prewound threaded inserts, a tap (corresponding to the outside diameter threads of the insert) and an installation tool. Most manufacturers also supply blister-packed thread repair inserts separately and a master kit with a variety of taps and inserts plus installation tools.

Before effecting a repair to a threaded hole, remove any snapped, broken or damaged bolts or studs. Penetrating oil can be used to free frozen threads; the offending item can be removed with locking pliers or with a screw or stud extractor. After the hole is clear, the thread can be repaired as follows.

A. Drill out the damaged threads with the specified drill. Drill completely through the hole or to the bottom of a blind hole.

B. With the tap supplied tap the hole to receive the threaded insert. Keep the tap well oiled and back it out frequently to avoid clogging the threads.

C. Screw the threaded insert onto the installation tool until the tang engages the slot. Screw the insert into the tapped hole until it is $\frac{1}{4}$ – $\frac{1}{2}$ turn below the top surface. After installation, break the tang off with a hammer and punch.

21 ENGINE REBUILDING

STANDARD TORQUE SPECIFICATIONS AND CAPSCREW MARKINGS

Newton-Meter has been designated as the world standard for measuring torque and will gradually replace the foot-pound and kilogram-meter torque measuring standard. Torquing tools are still being manufactured with foot-pounds and kilogram-meter

scales, along with the new Newton-Meter standard. To assist the repairman, foot-pounds, kilogram-meter and Newton-Meter are listed in the following charts, and should be followed as applicable.

SAE Grade Number		U.S. BOLTS											
		1 or 2			5			6 or 7			8		
Capscrew Head Markings Manufacturer's marks may vary. Three-line markings on heads below indicate SAE Grade 5.

METRIC BOLTS

Description	Torque ft-lbs. (Nm)			
Thread for general purposes (size x pitch (mm))	Head Mark 4		Head Mark 7	
6 x 1.0	2.2 to 2.9	(3.0 to 3.9)	3.6 to 5.8	(4.9 to 7.8)
8 x 1.25	5.8 to 8.7	(7.9 to 12)	9.4 to 14	(13 to 19)
10 x 1.25	12 to 17	(16 to 23)	20 to 29	(27 to 39)
12 x 1.25	21 to 32	(29 to 43)	35 to 53	(47 to 72)
14 x 1.5	35 to 52	(48 to 70)	57 to 85	(77 to 110)
16 x 1.5	51 to 77	(67 to 100)	90 to 120	(130 to 160)
18 x 1.5	74 to 110	(100 to 150)	130 to 170	(180 to 230)
20 x 1.5	110 to 140	(150 to 190)	190 to 240	(160 to 320)
22 x 1.5	150 to 190	(200 to 260)	250 to 320	(340 to 430)
24 x 1.5	190 to 240	(260 to 320)	310 to 410	(420 to 550)

CAUTION: Bolts threaded into aluminum require much less torque

NOTE: This engine rebuilding section is a guide to accepted rebuilding procedures. Typical examples of standard rebuilding procedures are illustrated.

CYLINDER HEAD RECONDITIONING

Procedure	Method
Identify the valves:	Invert the cylinder head, and number the valve faces front to rear, using a permanent felt-tip marker.
Remove the rocker arms (OHV engines only):	Remove the rocker arms with shaft(s) or balls and nuts. Wire the sets of rockers, balls and nuts together, and identify according to the corresponding valve.
Remove the camshaft (OHC engines only):	See the engine service procedures earlier in this book for details concerning specific engines.
Remove the valves and springs:	Using an appropriate valve spring compressor (depending on the configuration of the cylinder head), compress the valve springs. Lift out the keepers with needlenose pliers, release the compressor, and remove the valve, spring, and spring retainer.
Remove glow plugs and fuel injectors (Diesel engines only):	Label and remove all fuel injectors and glow plugs from the head. Glow plugs unscrew. See the appropriate car section for injector removal. Inspect glow plugs for bulges, cracks or signs of melting. Clean injector tips with a steel brush, then inspect for evidence of melting.

****Remove pre-combustion chamber inserts (Diesel engines only):**

Removing pre-combustion chamber with a drift (© G.M. Corp.)

****Remove the pre-combustion chambers using a hammer and a thin, blunt brass drift, inserted through the injector hole (or glow plug hole, whichever is more convenient). If chamber is to be reused, carefully remove all carbon from it.**

NOTE: Remove chamber only if being replaced, if a glow plug tip has broken off and must be removed, or if chamber is obviously damaged or loose.

Check the valve stem-to-guide clearance:

Checking the valve stem-to-guide clearance

Clean the valve stem with lacquer thinner or a similar solvent to remove all gum and varnish. Clean the valve guides using solvent and an expanding wire-type valve guide cleaner. Mount a dial indicator so that the stem is at 90° to the valve stem, as close to the valve guide as possible. Move the valve off its seat, and measure the valve guide-to-stem clearance by rocking the stem back and forth to actuate the dial indicator. Measure the valve stems using a micrometer, and compare to specifications, to determine whether stem or guide wear is responsible for excessive clearance.

CYLINDER HEAD RECONDITIONING

Procedure

Method

De-carbon the cylinder head and valves:

Chip carbon away from the valve heads, combustion chambers, and ports, using a chisel made of hardwood. Remove the remaining deposits with a stiff wire brush.

NOTE: *Ensure that the deposits are actually removed, rather than burnished.*

Removing carbon from the cylinder head

Hot-tank the cylinder head (cast iron heads only):
CAUTION: *Do not hot-tank aluminum parts.*

Have the cylinder head hot-tanked to remove grease, corrosion, and scale from the water passages.

NOTE: *In the case of overhead cam cylinder heads, consult the operator to determine whether the camshaft bearings will be damaged by the caustic solution.*

Degrease the remaining cylinder head parts:

Using solvent (i.e., Gunk), clean the rockers, rocker shaft(s) (where applicable), rocker balls and nuts, springs, spring retainers, and keepers. Do not remove the protective coating from the springs.

Check the cylinder head for warpage:

Place a straight-edge across the gasket surface of the cylinder head. Using feeler gauges, determine the clearance at the center of the straight-edge. Measure across both diagonals, along the longitudinal centerline, and across the cylinder head at several points. If warpage exceeds .003' in a 6' span, or .006' over the total length, the cylinder head must be resurfaced.

NOTE: *If warpage exceeds the manufacturer's maximum tolerance for material removal, the cylinder head must be replaced.*

When milling the cylinder heads of V-type engines, the intake manifold mounting position is altered, and must be corrected by milling the manifold flange a proportionate amount.

Checking cylinder head for warpage

****Porting and gasket matching:**

****Coat the manifold flanges of the cylinder head with Prussian blue dye. Glue intake and exhaust gaskets to the cylinder head in their installed position using rubber cement and scribe the outline of the ports on the manifold flanges. Remove the gaskets. Using a small cutter in a hand-held power tool gradually taper the walls of the port out to the scribed outline of the gasket. Further enlargement of the ports should include the removal of sharp edges and radiusing of sharp corners. Do not alter the valve guides.**

NOTE: *The most efficient port configuration is determined only by extensive testing. Therefore, it is best to consult someone experienced with the head in question to determine the optimum alterations.*

CYLINDER HEAD RECONDITIONING

Procedure

Method

*Knurling the valve guides:

Cut-away view of a knurled valve guide

*Valve guides which are not excessively worn or distorted may, in some cases, be knurled rather than replaced. Knurling is a process in which metal is displaced and raised, thereby reducing clearance. Knurling also provides excellent oil control. The possibility of knurling rather than replacing valve guides should be discussed with a machinist.

Replacing the valve guides:

NOTE: Valve guides should only be replaced if damaged or if an oversize valve stem is not available.

Valve guide removal tool

Depending on the type of cylinder head, valve guides may be pressed, hammered, or shrunk in. In cases where the guides are shrunk into the head, replacement should be left to an equipped machine shop. In other cases, the guides are replaced as follows: Press or tap the valve guides out of the head using a stepped drift (see illustration). Determine the height above the boss that the guide must extend, and obtain a stack of washers, their I.D. similar to the guide's O.D., of that height. Place the stack of washers on the guide, and insert the guide into the boss.

NOTE: Valve guides are often tapered or beveled for installation.

Using the stepped installation tool (see illustration), press or tap the guides into position. Ream the guides according to the size of the valve stem.

Valve guide installation tool (with washers used for installation)

Replacing valve seat inserts:

Replacement of valve seat inserts which are worn beyond resurfacing or broken, if feasible, must be done by a machine shop.

Resurfacing the valve seats using reamers:

Valve seat width and centering

Reaming the valve seat

Select a reamer of the correct seat angle, slightly larger than the diameter of the valve seat, and assemble it with a pilot of the correct size. Install the pilot into the valve guide, and using steady pressure, turn the reamer clockwise.

CAUTION: Do not turn the reamer counterclockwise.

Remove only as much material as necessary to clean the seat. Check the concentricity of the seat (see below). If the dye method is not used, coat the valve face with Prussian blue dye, install and rotate it on the valve seat. Using the dye marked area as a centering guide, center and narrow the valve seat to specifications with correction cutters.

NOTE: When no specifications are available, minimum seat width for exhaust valves should be $\frac{5}{64}$ ", intake valves $\frac{1}{16}$ ".

After making correction cuts, check the position of the valve seat on the valve face using Prussian blue dye.

NOTE: Do not cut induction hardened seats; they must be ground.

CYLINDER HEAD RECONDITIONING

Procedure

*Resurfacing the valve seats using a grinder:

Method

*Select a pilot of the correct size, and a coarse stone of the correct seat angle. Lubricate the pilot if necessary, and install the tool in the valve guide. Move the stone on and off the seat at approximately two cycles per second, until all flaws are removed from the seat. Install a fine stone, and finish the seat. Center and narrow the seat using correction stones, as described above.

Resurfacing (grinding) the valve face:

Using a valve grinder, resurface the valves according to specifications.

CAUTION: Valve face angle is not always identical to valve seat angle.

A minimum margin of $\frac{1}{32}$ " should remain after grinding the valve. The valve stem top should also be squared and resurfaced, by placing the stem in the V-block of the grinder, and turning it while pressing lightly against the grinding wheel.

NOTE: Do not grind sodium filled exhaust valves on a machine. These should be hand lapped.

FOR DIMENSIONS,
REFER TO
SPECIFICATIONS

Critical valve dimensions

Valve grinding by machine

CYLINDER HEAD RECONDITIONING

Procedure

Method

Checking the valve seat concentricity:

Checking valve seat concentricity using a dial gauge

Coat the valve face with Prussian blue dye, install the valve, and rotate it on the valve seat. If the entire seat becomes coated, and the valve is known to be concentric, the seat is concentric.

*Install the dial gauge pilot into the guide, and rest the arm on the valve seat. Zero the gauge, and rotate the arm around the seat. Run-out should not exceed .002".

*Lapping the valves:

NOTE: Valve lapping is done to ensure efficient sealing of resurfaced valves and seats.

Hand lapping the valves

*Invert the cylinder head, lightly lubricate the valve stems, and install the valves in the head as numbered. Coat valve seats with fine grinding compound, and attach the lapping tool suction cup to a valve head.

NOTE: Moisten the suction cup.

Rotate the tool between the palms, changing position and lifting the tool often to prevent grooving. Lap the valve until a smooth, polished seat is evident. Remove the valve and tool, and rinse away all traces of grinding compound.

**Fasten a suction cup to a piece of drill rod, and mount the rod in a hand drill. Proceed as above, using the hand drill as a lapping tool.

CAUTION: Due to the higher speeds involved when using the hand drill, care must be exercised to avoid grooving the seat. Lift the tool and change direction of rotation often.

Home made mechanical valve lapping tool

Check the valve springs:

Checking valve spring free length and squareness

Measuring valve spring test pressure

Place the spring on a flat surface next to a square. Measure the height of the spring, and rotate it against the edge of the square to measure distortion. If spring height varies (by comparison) by more than $\frac{1}{16}$ " or if distortion exceeds $\frac{1}{16}$ ", replace the spring.

**In addition to evaluating the spring as above, test the spring pressure at the installed and compressed (installed height minus valve lift) height using a valve spring tester. Springs used on small displacement engines (up to 3 liters) should be ± 1 lb. of all other springs in either position. A tolerance of ± 5 lbs. is permissible on larger engines.

CYLINDER HEAD RECONDITIONING

Procedure

Method

Install pre-combustion chambers (Diesel engines only)

Pre-combustion chambers are press-fit into the head. The chambers will fit only one way: on G.M. V8, align the notches in the chamber and head; on 1.8L 4 cyl., install lock ball into groove in chamber, then align lock ball in chamber with groove in cylinder head. Press the chamber into the head. Fit a piece of metal against the chamber face for protection. On 1.8L, after installation, grind the face of the chamber flush with the face of the cylinder head. On G.M. V8, use a 1 1/4 in. socket to install the chamber (the chamber should be flush $\pm .003$ in. to the face of the head).

Align the notches to install the pre-combustion chamber

Install fuel injectors and glow plugs (Diesel engines)

Before installing glow plugs, check for continuity across plug terminals and body. If no continuity exists, the heater wire is broken and the plug should be replaced.

*Install valve stem seals:

*Due to the pressure differential that exists at the ends of the intake valve guides (atmospheric pressure above, manifold vacuum below), oil is drawn through the valve guides into the intake port. This has been alleviated somewhat since the addition of positive crankcase ventilation, which lowers the pressure above the guides. Several types of valve stem seals are available to reduce blow-by. Certain seals simply slip over the stem and guide boss, while others require that the boss be machined. Recently, Teflon guide seals have become popular. Consult a parts supplier or machinist concerning availability and suggested usages.

NOTE: When installing seals, ensure that a small amount of oil is able to pass the seal to lubricate the valve guides; otherwise, excessive wear may result.

Valve stem seal installation

Install the valves:

Lubricate the valve stems, and install the valves in the cylinder head as numbered. Lubricate and position the seals (if used, see above) and the valve springs. Install the spring retainers, compress the springs, and insert the keys using needlenose pliers or a tool designed for this purpose.

NOTE: Retain the keys with wheel bearing grease during installation.

CYLINDER HEAD RECONDITIONING

Procedure

Method

Check valve spring installed height:

Valve spring installed height dimension

Measuring valve spring installed height

Measure the distance between the spring pad and the lower edge of the spring retainer, and compare to specifications. If the installed height is incorrect, add shim washers between the spring pad and the spring.

CAUTION: Use only washers designed for this purpose.

Install the camshaft (OHC engines only) and check end play:

See the engine service procedures earlier in this book for details concerning specific engines.

Inspect the rocker arms, balls, studs, and nuts (OHV engines only):

Visually inspect the rocker arms, balls, studs, and nuts for cracks, galling, burning, scoring or wear. If all parts are intact, liberally lubricate the rocker arms and balls, and install them on the cylinder head. If wear is noted on a rocker arm at the point of valve contact, grind it smooth and square, removing as little material as possible. Replace the rocker arm if excessively worn. If a rocker stud shows signs of wear, it must be replaced (see below). If a rocker nut shows stress cracks, replace it. If an exhaust ball is galled or burned, substitute the intake ball from the same cylinder (if it is intact), and install a new intake ball.

NOTE: Avoid using new rocker balls on exhaust valves.

Stress cracks in the rocker nuts

Replacing rocker studs (OHV engines only):

In order to remove a threaded stud, lock two nuts on the stud, and unscrew the stud using the lower nut. Coat the lower threads of the new stud with Loctite®, and install.

Two alternative methods are available for replacing pressed in studs. Remove the damaged stud using a stack of washers and a nut (see illustration). In the first, the boss is reamed .005-.006" oversize, and an oversize stud pressed in. Control the stud extension over the boss using washers, in the same manner as valve guides. Before installing the stud, coat it with white lead and grease. To retain the stud more positively drill a hole through the stud and boss, and install a roll pin. In the second method, the boss is tapped, and a threaded stud installed. Retain the stud using Loctite® Stud and Bearing Mount.

AS STUD BEGINS TO PULL UP, IT WILL BE NECESSARY TO REMOVE THE NUT AND ADD MORE WASHERS

Extracting a pressed-in rocker stud

Reaming the stud bore for oversize rocker studs

CYLINDER HEAD RECONDITIONING

Procedure	Method
Bleed the hydraulic lifters (diesel engines only):	After the cylinder heads are installed on G.M. V8 diesels, the valve lifters must be bled down before the crankshaft is turned. Failure to bleed down the lifters will cause damage to the valve train. See diesel engine rocker arm replacement procedure in Oldsmobile 88, 98, etc. car section for procedures. NOTE: When installing new lifters, prime by working the lifter plunger while submerged in clean kerosene or diesel fuel.

CYLINDER BLOCK RECONDITIONING

Procedure	Method
Checking the main bearing clearance:  Plastigage[®] installed on the lower bearing shell  Measuring Plastigage[®] to determine bearing clearance	Invert engine, and remove cap from the bearing to be checked. Using a clean, dry rag, thoroughly clean all oil from crankshaft journal and bearing insert. NOTE: Plastigage is soluble in oil; therefore, oil on the journal or bearing could result in erroneous readings. Place a piece of Plastigage along the full length of journal, reinstall cap, and torque to specifications. Remove bearing cap, and determine bearing clearance by comparing width of Plastigage to the scale on Plastigage envelope. Journal taper is determined by comparing width of the Plastigage strip near its ends. Rotate crankshaft 90° and retest, to determine journal eccentricity. NOTE: Do not rotate crankshaft with Plastigage installed. If bearing insert and journal appear intact, and are within tolerances, no further main bearing service is required. If bearing or journal appear defective, cause of failure should be determined before replacement. *Remove crankshaft from block (see below). Measure the main bearing journals at each end twice (90° apart) using a micrometer, to determine diameter, journal taper and eccentricity. If journals are within tolerances, reinstall bearing caps at their specified torque. Using a telescope gauge and micrometer, measure bearing I.D. parallel to piston axis and at 30° on each side of piston axis. Subtract journal O.D. from bearing I.D. to determine oil clearance. If crankshaft journals appear defective, or do not meet tolerances, there is no need to measure bearings; for the crankshaft will require grinding and/or undersize bearings will be required. If bearing appears defective, cause for failure should be determined prior to replacement.
Checking the connecting rod bearing clearance:	Connecting rod bearing clearance is checked in the same manner as main bearing clearance, using Plastigage. Before removing the crankshaft, connecting rod side clearance also should be measured and recorded. *Checking connecting rod bearing clearance, using a micrometer, is identical to checking main bearing clearance. If no other service is required, the piston and rod assemblies need not be removed.

CYLINDER HEAD RECONDITIONING

Procedure

Inspect the rocker shaft(s) and rocker arms (OHV engines only):

Disassemble the rocker shaft for inspection

Method

Remove rocker arms, springs and washers from rocker shaft. **NOTE:** Lay out parts in the order as they are removed. Inspect rocker arms for pitting or wear on the valve contact point, or excessive bushing wear. Bushings need only be replaced if wear is excessive, because the rocker arm normally contacts the shaft at one point only. Grind the valve contact point of rocker arm smooth if necessary, removing as little material as possible. If excessive material must be removed to smooth and square the arm, it should be replaced. Clean out all oil holes and passages in rocker shaft. If shaft is grooved or worn, replace it. Lubricate and assemble the rocker shaft.

Rocker arm-to-rocker shaft contact area

Inspect the camshaft bushings and the camshaft (OHC engines):

See next section.

Inspect the pushrods (OHV engines only):

Remove the pushrods, and, if hollow, clean out the oil passages using fine wire. Roll each pushrod over a piece of clean glass. If a distinct clicking sound is heard as the pushrod rolls, the rod is bent, and must be replaced.

*The length of all pushrods must be equal. Measure the length of the pushrods, compare to specifications, and replace as necessary.

Inspect the valve lifters (OHV engines only):

Checking the lifter face

Remove lifters from their bores, and remove gum and varnish, using solvent. Clean walls of lifter bores. Check lifters for concave wear as illustrated. If face is worn concave, replace lifter, and carefully inspect the camshaft. Lightly lubricate lifter and insert it into its bore. If play is excessive, an oversize lifter must be installed (where possible). Consult a machinist concerning feasibility. If play is satisfactory, remove, lubricate, and reinstall the lifter.

NOTE: 1981 and later G.M. diesel V8 valve lifters have roller cam followers. Check these for smooth operation and wear. The roller should rotate freely, but without excessive play. Check the rollers for missing or broken needle bearings. If the roller is pitted or rough, check the camshaft lobe for wear.

*Testing hydraulic lifter leak down (OHV gasoline engines only):

Typical exploded view of hydraulic valve lifter

Submerge lifter in a container of kerosene. Chuck a used pushrod or its equivalent into a drill press. Position container of kerosene so pushrod acts on the lifter plunger. Pump lifter with the drill press, until resistance increases. Pump several more times to bleed any air out of lifter. Apply very firm, constant pressure to the lifter, and observe rate at which fluid bleeds out of lifter. If the fluid bleeds very quickly (less than 15 seconds), lifter is defective. If the time exceeds 60 seconds, lifter is sticking. In either case, recondition or replace lifter. If lifter is operating properly (leak down time 15–60 seconds), lubricate and install it.

CYLINDER BLOCK RECONDITIONING

Procedure

Method

Removing the crankshaft:

Using a punch, mark the corresponding main bearing caps and saddles according to position (i.e., one punch on the front main cap and saddle, two on the second, three on the third, etc.). Using number stamps, identify the corresponding connecting rods and caps, according to cylinder (if no numbers are present). Remove the main and connecting rod caps, and place sleeves of plastic tubing over the connecting rod bolts, to protect the journals as the crankshaft is removed. Lift the crankshaft out of the block.

Connecting rod matched to cylinder with a number stamp

Scribe connecting rod matchmarks

Remove the ridge from the top of the cylinder:

RIDGE CAUSED BY CYLINDER WEAR

Cylinder bore ridge

In order to facilitate removal of the piston and connecting rod, the ridge at the top of the cylinder (unworn area; see illustration) must be removed. Place the piston at the bottom of the bore, and cover it with a rag. Cut the ridge away using a ridge reamer, exercising extreme care to avoid cutting too deeply. Remove the rag, and remove cuttings that remain on the piston.

CAUTION: If the ridge is not removed, and new rings are installed, damage to rings will result.

Removing the piston and connecting rod:

Invert the engine, and push the pistons and connecting rods out of the cylinders. If necessary, tap the connecting rod boss with a wooden hammer handle, to force the piston out.

CAUTION: Do not attempt to force the piston past the cylinder ridge (see above).

Removing the piston

CYLINDER BLOCK RECONDITIONING

Procedure	Method
Service the crankshaft:	Ensure that all oil holes and passages in the crankshaft are open and free of sludge. If necessary, have the crankshaft ground to the largest possible undersize. **Have the crankshaft Magnafluxed, to locate stress cracks. Consult a machinist concerning additional service procedures, such as surface hardening (e.g., nitriding, Tuftriding) to improve wear characteristics, cross drilling and chamfering the oil holes to improve lubrication, and balancing.
Removing freeze plugs:	Drill a small hole in the middle of the freeze plugs. Thread a large sheet metal screw into the hole and remove the plug with a slide hammer.
Remove the oil gallery plugs:	Threaded plugs should be removed using an appropriate (usually square) wrench. To remove soft, pressed in plugs, drill a hole in the plug, and thread in a sheet metal screw. Pull the plug out by the screw using pliers.
Hot-tank the block: NOTE: Do not hot-tank aluminum parts.	Have the block hot-tanked to remove grease, corrosion, and scale from the water jackets. NOTE: Consult the operator to determine whether the camshaft bearings will be damaged during the hot-tank process.
Check the block for cracks:	Visually inspect the block for cracks or chips. The most common locations are as follows: - Adjacent to freeze plugs. - Between the cylinders and water jackets. - Adjacent to the main bearing saddles. - At the extreme bottom of the cylinders. Check only suspected cracks using spot check dye (see introduction). If a crack is located, consult a machinist concerning possible repairs. **Magnaflux the block to locate hidden cracks. If cracks are located, consult a machinist about feasibility of repair.
Install the oil gallery plugs and freeze plugs:	Coat freeze plugs with sealer and tap into position using a piece of pipe, slightly smaller than the plug, as a driver. To ensure retention, stake the edges of the plugs. Coat threaded oil gallery plugs with sealer and install. Drive replacement soft plugs into block using a large drift as a driver. *Rather than reinstalling lead plugs, drill and tap the holes, and install threaded plugs.
*Check the deck height:	*The deck height is the distance from the crankshaft centerline to the block deck. To measure, invert the engine, and install the crankshaft, retaining it with the center main cap. Measure the distance from the crankshaft journal to the block deck, parallel to the cylinder centerline. Measure the diameter of the end (front and rear) main journals, parallel to the centerline of the cylinders, divide the diameter in half, and subtract it from the previous measurement. The results of the front and rear measurements should be identical. If the difference exceeds .005", the deck height should be corrected. NOTE: Block deck height and warpage should be corrected at the same time.

CYLINDER BLOCK RECONDITIONING

Procedure

Clean and inspect the pistons and connecting rods:

Removing the piston rings

Cleaning the piston ring grooves

Fit the pistons to the cylinders:

Measuring the piston prior to fitting

Assemble the pistons and connecting rods:

Using a ring expander, remove the rings from the piston. Remove the retaining rings (if so equipped) and remove piston pin.

NOTE: If the piston pin must be pressed out, determine the proper method and use the proper tools; otherwise the piston will distort.

Clean the ring grooves using an appropriate tool, exercising care to avoid cutting too deeply. Thoroughly clean all carbon and varnish from the piston with solvent.

CAUTION: Do not use a wire brush or caustic solvent on pistons.

Inspect the pistons for scuffing, scoring, cracks, pitting, or excessive ring groove wear. If wear is evident, the piston must be replaced. Check the connecting rod length by measuring the rod from the inside of the large end to the inside of the small end using calipers (see illustration). All connecting rods should be equal length. Replace any rod that differs from the others in the engine.

*Have the connecting rod alignment checked in an alignment fixture by a machinist. Replace any twisted or bent rods.

*Magnaflux the connecting rods to locate stress cracks. If cracks are found, replace the connecting rod.

Check the connecting rod length (arrow)

Using a telescope gauge and micrometer, or a dial gauge, measure the cylinder bore diameter perpendicular to the piston pin, $2\frac{1}{2}^\circ$ below the deck. Measure the piston perpendicular to its pin on the skirt. The difference between the two measurements is the piston clearance. If the clearance is within specifications or slightly below (after boring or honing), finish honing is all that is required. If the clearance is excessive, try to obtain a slightly larger piston to bring clearance within specifications. Where this is not possible, obtain the first oversize piston, and hone (or if necessary, bore) the cylinder to size.

Inspect piston pin, connecting rod small end bushing, and piston bore for galling, scoring, or excessive wear. If evident, replace defective part(s). Measure the I.D. of the piston boss and connecting rod small end, and the O.D. of the piston pin. If within specifications, assemble piston pin and rod.

CAUTION: If piston pin must be pressed in, determine the proper method and use the proper tools; otherwise the piston will distort.

CYLINDER BLOCK RECONDITIONING

Procedure

Method

Check the block deck for warpage:

Using a straightedge and feeler gauges, check the block deck for warpage in the same manner that the cylinder head is checked (see Cylinder Head Reconditioning). If warpage exceeds specifications, have the deck resurfaced.

NOTE: In certain cases a specification for total material removal (Cylinder head and block deck) is provided. This specification must not be exceeded.

Check the bore diameter and surface:

Visually inspect the cylinder bores for roughness, scoring, or scuffing. If evident, the cylinder bore must be bored or honed oversize to eliminate imperfections, and the smallest possible oversize piston used. The new pistons should be given to the machinist with the block, so that the cylinders can be bored or honed exactly to the piston size (plus clearance). If no flaws are evident, measure the bore diameter using a telescope gauge and micrometer, or dial guage, parallel and perpendicular to the engine centerline, at the top (below the ridge) and bottom of the bore. Subtract the bottom measurements from the top to determine taper, and the parallel to the centerline measurements from the perpendicular measurements to determine eccentricity. If the measurements are not within specifications, the cylinder must be bored or honed, and an oversize piston installed. If the measurements are within specifications the cylinder may be used as is, with only finish honing (see below).

NOTE: Prior to boring, check the block deck warpage, height and bearing alignment.

CAUTION: The 4 cyl. 140 G.M. engine cylinder walls are impregnated with silicone. Boring or honing can be done only by a shop with the proper equipment.

Measuring the cylinder bore with a dial gauge

Measuring cylinder bore with a telescope gauge

← CENTERLINE OF ENGINE →

A—AT RIGHT ANGLE TO CENTERLINE OF ENGINE
B—PARALLEL TO CENTERLINE OF ENGINE
Cylinder bore measuring points

Determining cylinder bore by measuring telescope gauge with a micrometer

Check the cylinder block bearing alignment:

Remove the upper bearing inserts. Place a straightedge in the bearing saddles along the centerline of the crankshaft. If clearance exists between the straightedge and the center saddle, the block must be alignbored.

Checking main bearing saddle alignment

CYLINDER BLOCK RECONDITIONING

Procedure

Method

Installing piston pin lock rings

Install the lock rings; ensure that they seat properly. If the parts are not within specifications, determine the service method for the type of engine. In some cases, piston and pin are serviced as an assembly when either is defective. Others specify reaming the piston and connecting rods for an oversize pin. If the connecting rod bushing is worn, it may in many cases be replaced. Reaming the piston and replacing the rod bushing are machine shop operations.

Clean and inspect the camshaft:

Checking the camshaft for straightness

Degrease the camshaft, using solvent, and clean out all oil holes. Visually inspect cam lobes and bearing journals for excessive wear. If a lobe is questionable, check all lobes as indicated below. If a journal or lobe is worn, the camshaft must be reground or replaced.

NOTE: If a journal is worn, there is a good chance that the bushings are worn.

If lobes and journals appear intact, place the front and rear journals in V-blocks, and rest a dial indicator on the center journal. Rotate the camshaft to check straightness. If deviation exceeds .001", replace the camshaft.

*Check the camshaft lobes with a micrometer, by measuring the lobes from the nose to base and again at 90° (see illustration). The lift is determined by subtracting the second measurement from the first. If all exhaust lobes and all intake lobes are not identical, the camshaft must be reground or replaced.

Camshaft lobe measurement

Replace the camshaft bearings (OHV engines only):

Camshaft removal and installation tool (typical)

If excessive wear is indicated, or if the engine is being completely rebuilt, camshaft bearings should be replaced as follows: Drive the camshaft rear plug from the block. Assemble the removal puller with its shoulder on the bearing to be removed. Gradually tighten the puller nut until bearing is removed. Remove remaining bearings, leaving the front and rear for last. To remove front and rear bearings, reverse position of the tool, so as to pull the bearings in toward the center of the block. Leave the tool in this position, pilot the new front and rear bearings on the installer, and pull them into position. Return the tool to its original position and pull remaining bearings into position.

NOTE: Ensure that oil holes align when installing bearings. Replace camshaft rear plug, and stake it into position to aid retention.

CYLINDER BLOCK RECONDITIONING

Procedure

Finish hone the cylinders:

Method

Chuck a flexible drive hone into a power drill, and insert it into the cylinder. Start the hone, and move it up and down the cylinder at a rate which will produce approximately a 60° cross-hatch pattern (see illustration).

NOTE: Do not extend the hone below the cylinder bore. After developing the pattern, remove the hone and recheck piston fit. Wash the cylinders with a detergent and water solution to remove abrasive dust, dry, and wipe several times with a rag soaked in engine oil.

Check piston ring end-gap:

Compress the piston rings to be used in a cylinder, one at a time, into that cylinder, and press them approximately 1" below the deck with an inverted piston. Using feeler gauges, measure the ring end-gap, and compare to specifications. Pull the ring out of the cylinder and file the ends with a fine file to obtain proper clearance.

CAUTION: If inadequate ring end-gap is utilized, ring breakage will result.

Install the piston rings:

Inspect the ring grooves in the piston for excessive wear or taper. If necessary, recut the groove(s) for use with an overwidth ring or a standard ring and spacer. If the groove is worn uniformly, overwidth rings, or standard rings and spacers may be installed without recutting. Roll the outside of the ring around the groove to check for burrs or deposits. If any are found, remove with a fine file. Hold the ring in the groove, and measure side clearance. If necessary, correct as indicated above.

NOTE: Always install any additional spacers above the piston ring.

The ring groove must be deep enough to allow the ring to seat below the lands (see illustration). In many cases, a "go-no-go" depth gauge will be provided with the piston rings. Shallow grooves may be corrected by recutting, while deep grooves require some type of filler or expander behind the piston. Consult the piston ring supplier concerning the suggested method. Install the rings on the piston, lowest ring first, using a ring expander.

NOTE: Position the ring markings as specified by the manufacturer (see car section).

CYLINDER BLOCK RECONDITIONING

Procedure

Method

Install the camshaft (OHV engines only):

Liberalily lubricate the camshaft lobes and journals, and install the camshaft.

CAUTION: *Exercise extreme care to avoid damaging the bearings when inserting the camshaft.*

Install and tighten the camshaft thrust plate retaining bolts. See the appropriate procedures for each individual engine.

Check camshaft end-play (OHV engines only):

Using feeler gauges, determine whether the clearance between the camshaft boss (or gear) and backing plate is within specifications. Install shims behind the thrust plate, or reposition the camshaft gear and retest end-play. In some cases, adjustment is by replacing the thrust plate.

*Mount a dial indicator stand so that the stem of the dial indicator rests on the nose of the camshaft, parallel to the camshaft axis. Push the camshaft as far in as possible and zero the gauge. Move the camshaft outward to determine the amount of camshaft endplay. If the endplay is not within tolerance, install shims behind the thrust plate, or reposition the camshaft gear and retest.

Install the rear main seal (where applicable):

See the appropriate procedures for each individual engine.

Install the crankshaft:

Thoroughly clean the main bearing saddles and caps. Place the upper halves of the bearing inserts on the saddles and press into position.

NOTE: *Ensure that the oil holes align.*

Press the corresponding bearing inserts into the main bearing caps. Lubricate the upper main bearings, and lay the crankshaft in position. Place a strip of Plastigage on each of the crankshaft journals, install the main caps, and torque to specifications. Remove the main caps, and compare the Plastigage to the scale on the Plastigage envelope. If clearances are within tolerances, remove the Plastigage, turn the crankshaft 90°, wipe off all oil and retest. If all clearances are correct, remove all Plastigage, thoroughly lubricate the main caps and bearing journals, and install the main caps. If clearances are not within tolerance, the upper bearing inserts may be removed, without removing the crankshaft, using a bearing roll out pin (see illustration). Roll in a bearing that will provide proper clearance, and retest. Torque all main caps, excluding the thrust bearing cap, to specifications. Tighten the thrust bearing cap finger tight. To properly align the thrust bearing, pry the crankshaft the extent of its axial travel several times, the last movement held toward the front of the engine, and torque the thrust bearing cap to specifications. Determine the crankshaft end-play (see below), and bring within tolerance with thrust washers.

Removal and installation of upper bearing insert using a roll-out pin

Home-made bearing roll-out pin

Aligning the thrust bearing

CYLINDER BLOCK RECONDITIONING

Procedure

Measure crankshaft end-play:

Checking crankshaft end-play with a dial indicator

Method

Mount a dial indicator stand on the front of the block, with the dial indicator stem resting on the nose of the crankshaft, parallel to the crankshaft axis. Pry the crankshaft the extent of its travel rearward, and zero the indicator. Pry the crankshaft forward and record crankshaft end-play.

NOTE: Crankshaft end-play also may be measured at the thrust bearing, using feeler gauges (see illustration).

Checking crankshaft end-play with a feeler gauge

Install the pistons:

Tubing used to protect crankshaft journals and cylinder walls during piston installation

Press the upper connecting rod bearing halves into the connecting rods, and the lower halves into the connecting rod caps. Position the piston ring gaps according to specifications (see car section), and lubricate the pistons. Install a ring compressor on a piston, and press two long (8") pieces of plastic tubing over the rod bolts. Using the tubes as a guide, press the pistons into the bores and onto the crankshaft with a wooden hammer handle. After seating the rod on the crankshaft journal, remove the tubes and install the cap finger tight. Install the remaining pistons in the same manner. Invert the engine and check the bearing clearance at two points (90° apart) on each journal with Plastigage.

NOTE: Do not turn the crankshaft with Plastigage installed. If clearance is within tolerances, remove all Plastigage, thoroughly lubricate the journals, and torque the rod caps to specifications. If clearance is not within specifications, install different thickness bearing inserts and recheck.

CAUTION: Never shim or file the connecting rods or caps. Always install plastic tube sleeves over the rod bolts when the caps are not installed, to protect the crankshaft journals.

RING COMPRESSOR

Installing a piston

CYLINDER BLOCK RECONDITIONING

Procedure

Check connecting rod side clearance:

Checking connecting rod side clearance

Method

Determine the clearance between the sides of the connecting rods and the crankshaft, using feeler gauges. If clearance is below the minimum tolerance, the rod may be machined to provide adequate clearance. If clearance is excessive, substitute an unworn rod, and recheck. If clearance is still outside specifications, the crankshaft must be welded and reground, or replaced.

Inspect the timing chain (or belt):

Visually inspect the timing chain for broken or loose links, and replace the chain if any are found. If the chain will flex sideways, it must be replaced. Install the timing chain as specified. Be sure the timing belt is not stretched, frayed or broken.

NOTE: If the original timing chain is to be reused, install it in its original position.

Check timing gear backlash and runout (OHV engines):

Checking camshaft gear backlash

Mount a dial indicator with its stem resting on a tooth of the camshaft gear (as illustrated). Rotate the gear until all slack is removed, and zero the indicator. Rotate the gear in the opposite direction until slack is removed, and record gear backlash. Mount the indicator with its stem resting on the edge of the camshaft gear, parallel to the axis of the camshaft. Zero the indicator, and turn the camshaft gear one full turn, recording the runout. If either backlash or runout exceed specifications, replace the worn gear(s).

Checking camshaft gear runout

Completing the Rebuilding Process

Following the above procedures, complete the rebuilding process as follows:

Fill the oil pump with oil, to prevent cavitating (sucking air) on initial engine start up. Install the oil pump and the pickup tube on the engine. Coat the oil pan gasket as necessary, and install the gasket and the oil pan. Mount the flywheel and the crankshaft vibration damper or pulley on the crankshaft. **NOTE:** Always use new bolts when installing the flywheel.

Inspect the clutch shaft pilot bushing in the crankshaft. If the bushing is excessively worn, remove it with an expanding puller

and a slide hammer, and tap a new bushing into place.

Position the engine, cylinder head side up. Lubricate the lifters, and install them into their bores. Install the cylinder head, and torque it as specified. Insert the pushrods (where applicable), and install the rocker shaft(s) (if so equipped) or position the rocker arms on the pushrods. Adjust the valves.

Install the intake and exhaust manifolds, the carburetor(s), the distributor and spark plugs. Adjust the point gap and the static ignition timing. Mount all accessories and install the engine in the car. Fill the radiator with coolant, and the crankcase with high quality engine oil.

Break-in Procedure

Start the engine, and allow it to run at low speed for a few minutes, while checking for leaks. Stop the engine, check the oil level, and fill as necessary. Restart the engine, and fill the cooling system to capacity. Check the point dwell angle and adjust the ignition timing and the valves. Run the engine at low to medium speed (800–2500 rpm) for approximately ½ hour, and retorque the cylinder head bolts. Road test the car, and check again for leaks.

Follow the manufacturer's recommended engine break-in procedure and maintenance schedule for new engines.

Diesel Maintenance 22

NOTE: Most procedures associated with diesel engined cars are similar to gas engined cars, although many parts of the diesel engine are unique compared to their gas engine counterparts. Standard maintenance and service procedures are given here while component removal, installation and adjustment procedures unique to diesel engines can be found in the appropriate section.

HOW THE DIESEL ENGINE WORKS

Four-stroke diesels require four piston strokes for the complete cycle of actions, exactly like a gasoline engine. The difference lies in how the fuel mixture is ignited. A diesel

engine does not rely on a conventional spark ignition to ignite the fuel mixture for the power stroke. Instead, a diesel relies on the heat produced by compressing air in the combustion chamber to ignite the fuel and produce a power stroke. This is known as a compression-ignition engine. No fuel enters the cylinder on the intake stroke, only air. At the end of the compression stroke, fuel is sprayed into the precombustion chamber (prechamber). The mixture ignites and spreads out into the main combustion chamber, forcing the piston downward (power stroke). The fuel/air mixture ignites because of the very high combustion chamber temperatures generated by the extraordinarily high compression ratios used in diesel engines. Typically, the compression ratios used in automotive diesels run any-

where from 16:1 to 23:1. A typical spark-ignition engine has a ratio of about 8:1. This is why a spark-ignition engine which continues to run after you have shut off the engine is said to be "dieseling". It is running on combustion chamber heat alone.

Designing an engine to ignite on its own combustion chamber heat poses certain problems. For instance, although a diesel engine has no need for a coil, spark plugs, or a distributor, it does need what are known as "glow plugs". These superficially resemble spark plugs, but are only used to warm the combustion chambers when the engine is cold. Without these plugs, cold starting would be impossible, due to the enormously high compression ratios and the characteristics of the diesel fuel itself.

All diesel engines use fuel injection, be-

4-stroke diesel engine cycle. At *air intake* (1), rotation of the crankshaft drives a toothed belt that turns the camshaft, opening the intake valve. As the piston moves down, a vacuum is created, sucking fresh air into the cylinder, past the open intake valve. *Air compression* (2): As the piston moves up, both valves are closed, and the air is compressed about 23 times smaller than its original volume. The compressed air reaches a temperature of about 1,650°F., far above the temperature needed to ignite diesel fuel. *Fuel injection and compression* (3): As the piston reaches the top of the stroke, the air temperature is at its maximum. A fine mist of fuel is sprayed into the prechamber, where it ignites, and the flame front spreads rapidly into the combustion chamber. The piston is forced downward by the pressure (about 500 psi) of expanding gases. *Exhaust* (4): As the energy of combustion is spent and the piston begins to move upward again, the exhaust valve opens, and burnt gases are forced out past the open valve. As the piston starts down, the exhaust valve closes, the intake valve opens, and the air intake stroke begins again.

Increasingly, modern diesel engines are being equipped with turbochargers, exhaust gas-driven devices that force more air into the engine to increase power output

cause unlike spark-ignited engines, the fuel cannot be drawn through the intake tract

Cutaway view of typical 4-cylinder diesel engine.

and into the cylinders. The introduction of fuel into a diesel engine must be precisely timed so that each cylinder "fires" at the proper moment. Also, the fuel injection pressure (at the cylinder) must be great enough to overcome the high compression pressures, and properly atomize the fuel without the aid of a moving air mass (as in a carbureted gas engine). It is not uncommon for diesel engine fuel injection pressures to be set at 1500-1700 psi.

Diesel engines share many of their basic mechanical components with gasoline engines, though the cylinder block, head(s), crankshaft, connecting rods, pistons, etc., are manufactured to be much stronger for use in diesel engines. The additional strength of the components is necessary due to the very high cylinder pressure generated within the diesel engine.

Maintenance and Service Procedures

Maintenance procedures for the diesel engine generally fall into three categories:

1. Fuel system
2. Starting system
3. Engine mechanical systems

Of these, the fuel system is usually the most likely source of engine troubles, and should be high on the list for regular maintenance attention.

FUEL SYSTEM

The typical diesel engine fuel system consists of fuel tank, fuel feed and return lines, mechanical fuel injection pump, fuel injectors and lines, and a large capacity fuel filter. On some models, the engine may also be equipped with a small, low pressure fuel pump which feeds the injection pump.

In addition to these, the air intake system (air cleaner, inlet manifold) should be checked over regularly to insure unrestricted air flow into the cylinders.

In operation, fuel is sucked out of the fuel tank by the injection pump (or its feed pump) and fed by the injection pump to the injectors in the cylinder head at a very high pressure. Before the fuel is allowed to enter the main injection pump, it passes through a specially built fuel filter which traps solid particles (and water on some models) in the fuel. Fuel that is not used is pumped back to the fuel tank through the fuel return lines. This recirculated fuel helps cool the injection pump.

Air Cleaner

On a gasoline engine, the volume of air taken in by the engine is controlled by throttle valves. When the throttle valves are closed (engine idling), air intake is restricted. When the throttle valves are wide open (accelerator pedal to the floor), the engine draws

Typical diesel engine fuel system schematic

Because a greater quantity of air passes through the diesel engine, air filter maintenance is particularly important. Most diesel air filters on passenger cars are similar to their counterparts on gasoline engines.

in the maximum amount of air it possibly can. This applies to both carbureted and fuel injected gasoline engines.

The speed (rpm) of a diesel engine is controlled by the quantity of fuel which is injected into the engine; no air metering restrictions (throttle valves) are used. Because of this, diesel engines ingest as much air as they possibly can under all conditions. A much greater volume of air passes through the air cleaner of a diesel per mile, therefore, diesel air filters must either be larger or the filter replacement intervals more frequent than those of a similarly sized gasoline engine.

One word of caution: never remove the air cleaner on a diesel with the engine running, and never run the engine with the air cleaner removed. The volume of air drawn through the inlet manifold is very great, and, because the inlet manifold is unobstructed, anything drawn into the inlet manifold (air cleaner wing nut, etc.) goes straight to the combustion chambers, where it can cause major engine damage.

Fuel Filter

The diesel engine fuel filter is usually larger than the filter used on gasoline engines. The extra capacity is needed to trap the suspended particles in diesel fuel, which is generally "dirtier" than gasoline.

Many diesel engines use a spin-on type primary fuel filter.

On some engines, the fuel filter looks like a second engine oil filter, and is removed and installed in the same manner as the canister-type oil filter.

The fuel filter must be changed according to the manufacturer's suggested interval. See the owner's manual for information.

After installing the fuel filter start the engine and check for leaks. Run the engine for about two minutes, then stop the engine for the same amount of time to allow any air trapped in the injection system to bleed off.

Many diesels also have a small, in-tank filter which is usually maintenance-free.

A smaller, in-line secondary filter is used on many engines.

Check the tightness of the clamps securing the injector lines. Note that the injector lines are all the same length.

Mercedes-Benz diesel engines use this stop switch, which shuts off fuel delivery

Water In Fuel

Diesel fuel is a hydrophilic fluid, that is, it naturally attracts water. Since diesel fuel and water do not mix, the water remains floating beneath the fuel at the bottom of the tank. This water must be removed every now and then, or it will be sucked into the fuel circuit and pass through the injection system, causing corrosion and possible component failure (injection pumps can cost up to \$1,000). Water in the fuel system will also cause the engine to run poorly, if at all.

Most diesel fuel tanks are equipped with

a separator which can isolate from 1 to 3 gallons of water from the fuel.

Many diesels are also equipped with "Water in Fuel" lights in the dashboard which warn of the presence of water in the fuel tank. These warning systems can be installed on models not so equipped.

On some diesels, there is a water catcher in the bottom of the fuel filter which can easily be bled off. In addition, there are several bolt-on water filters on the market which attach to the fuel line under the hood and separate water from the fuel. Depending on which kind you buy, draining water from the system is simply a matter of opening the petcock at the bottom of the filter and letting the water drain out, or, if money is no object, a separator is available on which water is drained from the filter simply by activating a switch on the dashboard.

Removing Water from the Fuel Tank

Treat diesel fuel with the same respect you would gasoline, and after the procedure, properly dispose of the fuel.

1. Remove the fuel tank cap.
2. Connect a pump or siphon hose to the 1/4 in. fuel return hose (smaller of the two fuel hoses) above the rear axle, or under the hood near the fuel pump (on the passenger's side of the engine, near the front).
3. Siphon until all water is removed from the tank. Do not use your mouth to create siphon vacuum, EVER! The best method is to siphon the water into a large capacity see-through container. The water will collect at the bottom of the container.
4. When all water has been removed from the tank, be sure to reinstall the fuel return hose and fuel cap.

NOTE: If the entire fuel system (not just the tank) is contaminated by water, the vehicle must be stopped immediately and the fuel system must be purged. This includes draining and removing the fuel tank, blowing low pressure compressed air backwards through the fuel feed and return lines, and bleeding the water out of all injection components. This job should be referred to a qualified technician.

Cold Weather Fuel System Maintenance

CAUTION

NEVER use "starting aids" (e.g.—ether) to help start a diesel engine—serious engine damage will result.

As will be explained later under "Fuel Recommendations", diesel fuel tends to become "cloudy", or thicker, as the temperature drops. The thicker the diesel fuel becomes, the slower it flows through the fuel system, until finally it stops flowing altogether somewhere near the bottom of the thermometer.

22 DIESEL MAINTENANCE

One way to fight sluggish fuel flow is to use winterized blends of diesel fuel, straight No. 1 diesel fuel or add cold weather additives to the fuel to improve flow in cold weather.

NOTE: Consult your owners manual for recommendations and be sure to use a fuel conditioner compatible with water separators.

Another way is to install an aftermarket fuel system pre-heater. These are generally canisters which connect into the fuel line and use coolant from the engine cooling system to heat the fuel before it reaches the injection pump. The one drawback with this system is the engine must be started before the pre-heater begins to work. Also available are electric fuel warmers. These pre-heat the fuel going into the filter and can be used in conjunction with the coolant-type fuel heater.

Cold weather additives and fuel conditioners can help improve cold weather flow of diesel fuel.

Some manufacturers offer an optional electric diesel fuel heater and engine block heaters. The fuel heater is thermostatically controlled to heat the fuel before it enters the fuel filter when fuel temperature is 20°F or lower. The fuel heater works only when the ignition key is in the RUN position. On these models, the fuel tank filter has a bypass valve which allows fuel to flow to the heater when the tank filter is covered with fuel wax. The engine block heater is equipped with an electrical cord wrapped up in the engine compartment. The cord

Some diesel engines come equipped with a built-in heating system to keep the engine warm in cold temperatures.

Most OEM heaters work from 110-volt house current.

Some aftermarket diesel fuel warmers are thermostatically controlled heat exchangers that use engine coolant to keep diesel fuel above its "cloud point," the temperature at which it gels and forms wax that can clog a fuel system.

plugs into regular 110 volt household current. The block heater can be used, according to the type of oil in the crankcase, up to eight hours or overnight to warm up the block.

STARTING SYSTEM

The diesel starting system includes one (sometimes two) heavy duty batteries, the starter, and the glow plug circuit. In addition to the heavy duty battery(ies), the majority of diesel engines also have starters and battery cables designed specifically as heavy duty items for diesel usage only. Because of the high compression of any diesel, the torque required to turn the engine is much greater than a gasoline engine. The starter must be powerful enough to handle the increased load; the battery cables must be thick enough to withstand the heat generated by the starter load.

For battery maintenance, see the regular "Maintenance" section. Jump starting procedures for a dual battery car are given below. Starter maintenance is included in the appropriate car section.

The glow plug circuit is used on the diesel to initially start the engine. When the ignition switch is turned to the ON position, a light will come on in the instrument panel signalling that the glow plugs are preheating the combustion chambers. After a certain interval (depending on how cold the engine is), the light will go off. This signals that the starter may be engaged and the engine started. If the glow plug circuit mal-

functions, especially in cold weather, the engine will be almost impossible to start.

CAUTION

NEVER use "starting aids" (e.g.—ether) to help start a diesel engine—serious engine damage will result.

Glow Plug Testing

To test each individual glow plug, disconnect the busbar and/or wire connector from the glow plug and connect a test light between the glow plug terminal and the positive battery terminal. If the test light lights, the glow plug is working. Replace individual glow plugs which do not work.

NOTE: Some diesel engines are equipped with either "slow glow" or "fast glow" glow plugs. Do not attempt to interchange any parts of these two glow plug systems.

To test the glow plug circuit, connect a test light to the terminal of one of the glow plugs (glow plug wiring still attached) and turn the ignition to the heating position. The test light should light for a short while. If not, the glow plug circuit is malfunctioning and must be diagnosed and repaired.

NOTE: Perform this operation on a cold engine only.

Jump-Starting a Dual Battery Diesel

Some diesels are equipped with two 12 volt batteries. The batteries are connected in parallel circuit (positive terminal to positive terminal, negative terminal to negative terminal). Hooking the batteries up in parallel circuit increases battery cranking power without increasing total battery voltage output (12 volts). On the other hand, hooking two 12 volt batteries up in a series circuit (positive terminal to negative terminal, positive terminal to negative terminal) increases total battery output to 24 volts (12 volts + 12 volts).

CAUTION

NEVER hook the batteries up in a series circuit; **SEVERE** electrical system damage will result.

In the event that a dual battery diesel must be jump started, use the following procedure.

1. Open the hood and locate the batteries.

2. Position the donor car so that the jumper cables will reach from its battery (must be 12 volt, negative ground) to the appropriate battery in the diesel. Do not allow the cars to touch.

3. Shut off all electrical equipment on both vehicles. Turn off the engine of the donor car, set the parking brakes on both vehicles and block the wheels. Also, make sure both vehicles are in Neutral (manual

transmission models) or Park (automatic transmission models).

4. Using the jumper cables, connect the positive (+) terminal of the donor car battery to the positive terminal of one (not both) of the diesel batteries.

5. Using the second jumper cable, connect the negative (-) terminal of the donor battery to a solid, stationary, metallic point on the diesel (alternator bracket, engine block, etc.). Be very careful to keep the jumper cables away from moving parts (cooling fan, alternator belt, etc.) on both vehicles.

6. Start the engine of the donor car and run it at moderate speed.

7. Start the engine of the diesel.

8. When the diesel starts, disconnect the battery cables in the reverse order of attachment.

ENGINE MECHANICAL SYSTEMS

Included are engine lubrication and engine compression.

Although diesel engines are very low in carbon monoxide (CO) and hydrocarbon (HC) emissions, "particulate" emission output is very high from diesel engines. This is evident from the black smoke emitted by diesels, which is most noticeable during hard acceleration or high engine loads. The particulates are made up of mostly soot (carbon) and sulphur particles. The majority of these particulates are released into the atmosphere. However, some of the particulate matter, because it is produced within the engines cylinders, is left inside the engine and gradually contaminates the engine oil. This contamination makes the oil corrosive, due to the sulphur, and abrasive, due to the carbon. Serious engine damage will result if these contaminants continue to accumulate in the oil. Engine oil and filters of diesel engines must be changed more frequently than those of gasoline engines, due to the increased rate at which the contaminants form in the diesel. Consult the "Maintenance" section for oil and filter change procedures. The manufacturer's recommended oil change interval will be given in the owner's manual. An explanation of diesel engine oils is given at the end of this section.

As explained earlier, very high cylinder compression is the key to the operation of the diesel engine. The normal compression of most gasoline engines will rarely exceed 180 psi; whereas with diesel engines, compression pressures of 350-400 psi are commonplace.

CAUTION

DO NOT attempt to check the compression of a diesel engine with a standard compression gauge—personal injury could result. A special, high pressure compression gauge is needed to safely check the compression of any diesel.

A diesel compression tester kit with adapters (Courtesy S & G Tools).

Compression Test

1. Remove the air cleaner.
 2. Disconnect the wire from the fuel shutoff solenoid terminal of the injection pump.
 3. Disconnect the wires from the glow plugs and remove all glow plugs.
 4. Screw compression gauge into the glow plug hole in the cylinder being checked.
 5. Crank the engine, allowing six "puffs" for each cylinder.
- The lowest reading cylinder should not be less than 70% of the highest, and no cylinder should be less than 275 pounds.

Idle Speed Adjustments

Idle speed adjustment procedures for individual diesel engines are given in the car section. Consult the following section for procedures to measure idle speed

Connecting a Tachometer to a Diesel Engine

As mentioned earlier, the diesel engine does not require an electrical ignition system. Because of this, problems arise when attempts are made to connect a tachometer to the engine for the purpose of idle adjustments, etc. The average gasoline engine tachometer senses the ignition spark pulses and converts them into a readable engine rpm signal. This type of tachometer is use-

less on the diesel engine, because of the diesel's compression ignition system.

There are several magnetic and photoelectric tachometers available from various tool manufacturers which were designed specifically for use with the diesel engine. These units can run into a little more money than the average do-it-yourselfer may be willing to spend, in which case any adjustments requiring the monitoring of engine rpm should be performed by a competent service technician.

The newest equipment for measuring idle speed on a diesel engine includes (clockwise from lower left) a digital diesel tach display, photomagnetic pick-up with display input, magnetic swivel base (holder), DC power source for the display unit and a roll of magnetic tape.

The magnetic tape is attached to any moving part (such as the balancer). The pieces of tape must be at least 6 inches apart. Aim the photomagnetic pick-up at the moving object and adjust the position of the pick-up until the "on-target" light is lit. Flip the switch to TACH and read the rpm.

Diesel Engine Precautions

- Never run the engine with the air cleaner removed: if anything is sucked into the inlet manifold it will go straight to the combustion chambers, or jam behind a valve.
- Never wash a diesel engine: the reaction of a warm fuel injection pump to cold (or even warm) water can ruin the pump.
- Never operate a diesel engine with one or more fuel injectors removed unless fully familiar with injector testing procedures: some diesel injection pumps spray fuel at up to 1400 psi—enough pressure to allow the fuel to penetrate your skin.
- Do not skip engine oil and filter changes.
- Strictly follow the manufacturer's oil and fuel recommendations as given in the owner's manual.
- Do not use home heating oil as fuel for your diesel.
- Do not use "starting aids" (e.g.—ether) in the automotive diesel engine, as these "aids" can cause severe internal engine damage.
- Do not run a diesel engine with the "Water in Fuel" warning light on in the dashboard.
- If removing water from the fuel tank yourself, use the same caution you would use when working around gasoline engine fuel components.
- Do not allow diesel fuel to come in contact with rubber hoses or components on the engine, as it can damage them.

Fuel and Oil Recommendations

FUEL

Fuel makers produce two grades of diesel fuel, No. 1 and No. 2, for use in automotive diesel engines. Generally speaking, No. 2 fuel is recommended over No. 1 for driving

in temperatures above 20°F. In fact, in many areas, No. 2 diesel is the only fuel available. By comparison, No. 2 diesel fuel is less volatile than No. 1 fuel, and gives better fuel economy. No. 2 fuel is also a better injection pump lubricant.

Two important characteristics of diesel fuel are its cetane number and its viscosity.

The cetane number of a diesel fuel refers to the ease with which a diesel fuel ignites. High cetane numbers mean that the fuel will ignite with relative ease or that it ignites well at low temperatures. Naturally, the lower the cetane number, the higher the temperature must be to ignite the fuel. Most commercial fuels have cetane numbers that range from 35 to 65. No. 1 diesel fuel generally has a higher cetane rating than No. 2 fuel.

Cetane (diesel engine) versus octane (gasoline engine) ratings. The higher the cetane number, the faster the fuel burns

Viscosity is the ability of a liquid, in this case diesel fuel, to flow. Using straight No. 2 diesel fuel below 20°F can cause problems, because this fuel tends to become cloudy, meaning wax crystals begin forming in the fuel. In extreme cold weather, No. 2 fuel can stop flowing altogether. In either case, fuel flow is restricted, which can result in a "no start" condition or poor engine performance. Fuel manufacturers often "winterize" No. 2 diesel fuel by using various fuel additives and blends (No. 1 diesel fuel, kerosene, etc.) to lower its winter-time viscosity. Generally speaking, though, No. 1 diesel fuel is more satisfactory in extremely cold weather.

NOTE: No. 1 and No. 2 diesel fuels will mix and burn with no ill effects, although the engine manufacturer will undoubtedly recommend one or the other. Consult the owner's manual for information.

Depending on local climate, most fuel manufacturers make winterized No. 2 fuel available seasonally.

Many automobile manufacturers publish pamphlets giving the locations of diesel fuel stations nationwide. Contact the local dealer for information.

Do not substitute home heating oil for automotive diesel fuel. While in some cases, home heating oil refinement levels equal those of diesel fuel, many times they are far below diesel engine requirements. The result of using "dirty" home heating oil will be a clogged fuel system, in which case the entire system may have to be dismantled and cleaned.

One more word on diesel fuels. Don't thin diesel fuel with gasoline in cold weather. The lighter gasoline, which is more explosive, will cause rough running at the very least, and may cause extensive engine damage if enough is used.

OIL

Diesel engines require different engine oil from those used in gasoline engines. Besides doing the things gasoline engine oil does, diesel oil must also deal with increased engine heat and the diesel blow-by gases, which create sulphuric acid, a high corrosive.

Under the American Petroleum Institute (API) classifications, gasoline engine oil codes begin with an "S", and diesel engine oil codes begin with a "C". This first letter designation is followed by a second letter code which explains what type of service (heavy, moderate, light) the oil is meant for. For example, the top of a typical oil can will include: "API SERVICES SC, SD, SE, CA, CB, CC". This means the oil in the can is a good, moderate duty engine oil when used in a diesel engine.

It should be noted here that the further

COMPARISON OF #1 AND #2 DIESEL FUEL

Requirement	1-D	2-D
Flash Point, °F minimum	100	125
Cetane Number, minimum	40	40
Viscosity at 100°F, Centistokes		
Minimum	1.4	2.0
Maximum	2.5	4.3
Water and Sediment, % by volume maximum	Trace	0.05
Sulfur, % by weight maximum	0.5	0.5
Ash, % by weight maximum	0.01	0.01

Flash Point: The temperature at which diesel fuel ignites when exposed to a flame in the open air.

Cetane Number: See text

down the alphabet the second letter of the API classification is, the greater the oil's protective qualities are (CD is the severest duty diesel engine oil, CA is the lightest duty oil, etc.). The same is true for gasoline engine oil classifications (SF is the severest duty gasoline engine oil, SA is the lightest duty oil, etc.).

Many diesel manufacturers recommend an oil with both gasoline and diesel engine API classifications. Consult the owner's manual for specifications.

The top of the oil can will also contain an SAE (Society of Automotive Engineers) designation, which gives the oil's viscosity. A typical designation will be: SAE 10W-30, which means the oil is a "winter" viscosity oil, meaning it will flow and give protection at low temperatures.

On the diesel engine, oil viscosity is critical, because the diesel is much harder to start (due to its higher compression) than a gasoline engine. Obviously, if you fill the crankcase with a very heavy oil during winter (SAE 20W-50, for example), the starter is going to require a lot of current from the battery to turn the engine. And, since batteries don't function well in cold weather in the first place, you may find yourself stranded some morning. Consult the owner's manual for recommended oil specifications for the climate you live in.

LUBE OIL ANALYSIS

From an oil sample a laboratory can diagnose many potential engine problems—from piston wear to impending bearing failure. What's more, the laboratory can spot them quicker, and with greater accuracy. Just as easily, the lab can give the diesel a clean bill of health, saving the car owner unnecessary servicing and other routine preventive maintenance, costly in time and money.

There's nothing new about engine lube oil analysis. Thousands of the nation's trucks and buses regularly have their engine's lube oil analyzed by laboratories specializing in this type of work. What is new is the availability of lube oil analysis to individual vehicle owners rather than, as before, almost exclusively to companies operating fleets of diesel equipment.

Lube oil analysis can be a valuable indicator of internal engine condition.

Here's how lube oil analysis works. You write one of the several laboratories that offer individual diesel vehicle owners lube analysis service. By return mail you'll receive an oil sampling kit. It will probably contain a two-ounce plastic oil sampling container with a screw-on plastic top. Instructions tell you how to take the sample. Usually, a lab-bound sample of diesel lube oil may be taken in any of three ways, but always right after the engine has been shut off, so that the sampled oil is as close as possible to normal engine operating temperature. That's important to assure that the lab's test will be accurate. Oil samples can be taken during normal oil changes, when lube oil is drained anyway. Between oil changes, a sample can be drawn from the engine through the dipstick tube (where you normally check the oil's level). In drawing an oil sample from the dipstick tube, a small suction bulb fitted with a length of disposable tubing is used. The tubing is merely inserted into the dipstick tube, the suction bulb depressed, and the oil sample drawn. The third method of sampling is by loosening the drain plug on the engine's bypass oil filter (if your diesel has one). A little oil is caught in the lube sampling container. In all cases, extreme cleanliness is a must, so as not to contaminate the sample with dirt, grease, or other substances not actually found inside the engine. For example, using a rag that contains solvents, metal filings, or other impurities can contaminate the oil sample, leading to false and even alarming lab reports. A bit of technique is required: In taking a sample of lube oil during a routine oil drain, about half of the crankcase's lube oil should be allowed to drain out before the sample is taken. The sample taken, the date, make and model of the engine, its mileage, mileage since last oil change, and sometimes oil type are noted on the container's label, and the container is mailed to the laboratory.

Shortly, you'll receive the lab's report, which, based on a number of tests, including spectrochemical analysis (using a spectrometer, which can detect the presence of virtually all basic elements and contaminants), tells what's in the oil in what quantities and analyzes both the probable source of what was found and whether it indicates trouble. For one example, the finding of more than trace amounts of copper in an oil sample may strongly point to excessive bearing wear in a particular diesel whose bearings contain copper. Some analyses report on as many as eighteen basic elements that may be found in a diesel's lube oil sample, and in the report's "recommendation" may pinpoint their probable source—as, "indicates piston ring wear." Also indicated is the presence of such contaminants as water, solids (the products of oxidation and engine blow-by), and fuel dilution. Noted, too, is the lubricity of the sample—whether, or not, in the lab's opinion, it is still doing its internal engine lubricating job.

NOTE: Never use lube analysis and a lab's report of "good oil" to extend, beyond the manufacturer's recommendation, the mileage period between oil changes. Follow the manufacturers recommendations.

The more frequently an engine is lube-sampled, the more accurate and meaningful the lab's reports. Infrequent samplings, although they can spot sudden, unusual changes in internal engine condition, may fail to show the gradual deterioration of engine parts. Ideally, you should have the laboratory analyze a lube sample every other oil change. For most automobile diesels, that's every 6,000 miles. Analysis costs from \$7 to \$11 per sample. Drive an average 18,000 miles a year and you'd change your diesel's oil three times. In that time, you'd submit three samples to the lab at an annual lube analysis cost of \$21 to \$33.

Aftermarket Fuel System Accessories

Due to reasons described previously, most diesel engine problems can be attributed to either fuel contamination or cold weather fuel performance characteristics. Diesel-engined vehicle manufacturers have designed and installed various systems to combat these problems, but ultimately, their best efforts are limited by cost.

Inconvenience is a major concern to diesel owners. If water accumulates (in substantial quantities) in the diesel fuel system, the fuel and water must be siphoned from the fuel tank and purged from the remainder of the fuel system. It goes without saying that this operation is a messy, time-consuming process. Even if the vehicle is equipped with a water/fuel separator having a drain valve, the owner must manually open the valve from either under the hood or beneath the vehicle.

Although the fuel filter installed by the manufacturer offers adequate performance when maintained properly, the addition of another, separate diesel fuel filter is a wise improvement.

If you live in an extremely cold climate, you've probably experienced cold starting problems due to fuel "waxing", plugged filters, "gelled" fuel, etc. If your vehicle is not factory-equipped with the optional fuel line or cylinder block heaters, these

Aftermarket fuel filter/water separator and fuel line heater

heaters can be purchased from the aftermarket (retail auto parts manufacturers). The installation of either of these items can improve cold-starting dramatically.

WATER/FUEL SEPARATORS

Centrifugal Action

Sometimes referred to as a "cyclonic" water/fuel separator, this device uses baffles which spin the fuel as it comes through the separator inlet. Since water is heavier than diesel fuel, the water will spin away from the fuel, sink to the bottom of the separator, and collect in the sediment bowl.

This type of separator is most efficient in dealing with large water droplets. If the water is in emulsion with the fuel, that is, if the water is equally dispersed through the fuel in very small droplets, some of the water will remain with the fuel to travel through the fuel system.

Coalescing Action

In this type of separator, the fuel must pass through a coalescent filtering media before proceeding through the fuel system. The idea behind the coalescent media is to trap even the smallest droplets of water on the media. As the small droplets combine into larger, heavier droplets, gravity acts on the droplets to pull them downward, off of the media and into the sediment bowl.

FUEL FILTER/SEPARATOR COMBINATION UNITS

Most separators of either the centrifugal or coalescent types are available with disposable fuel filtering elements which are built into the separator unit. If your car already has a large, disposable filter, it would probably be more cost-effective to stay with a separator only, and to change the factory-equipped filter at the recommended intervals. Should your vehicle have a fairly small filter, and/or an inconveniently located water drain (or none at all), choose the filter/separator combination. The filter/separator offers both increased fuel filtering ability and efficient water separation.

Convenience Add-Ons

Available with many separators and filter/separators are items such as dash-mounted

water-in-fuel indicator lamps, audible water-in-fuel alarms, and dash-controlled water ejection systems. A properly chosen system would warn you of water in the fuel, and allow you to eject the water by simply "flipping" a dash-mounted switch.

Installing a Separator

Clear installation instructions and the necessary installation parts will be provided with the separator kit. Follow those instructions exactly. A general list of suggestions follows:

1. Fuel additives should not be used unless approved by the separator manufacturer.
2. Do not install a separator within 4" of any exhaust system component.
3. If plastic fittings are supplied with the kit, do not replace them with metal fittings. Also, use extreme caution when tightening the fittings, especially those made of plastic.
4. Use a fuel-proof sealer on all fitting threads, only if the threads are not factory-coated with sealer.
5. Use only fuel-proof hoses for the installation.
6. Do not eliminate the original equipment fuel filter, even if a filter/separator is installed.
7. For new car warranty purposes, a filter/separator should be located BEFORE the original equipment filter. The fuel must pass through the original filter last, before entering the fuel injection pump.
8. If any type of fuel line heater is installed, it is best to position the heater between the fuel tank and the separator inlet.
9. To ease the job of the separator, the separator should be installed between the fuel transfer pump and the tank (unless the separator manufacturer specifies otherwise). Fuel and water which have been churned through the fuel transfer pump will be more difficult to separate.
10. Be sure that any wiring (for warning lamps, water ejection, etc.) is routed and connected properly. If the wiring must pass through a drilled hole, be sure to use a rubber grommet between the drilled component(s) and the wire to prevent damage to the wire.

FUEL LINE HEATERS

Two popular types of fuel line heaters are available for diesel passenger cars. Both

types raise the temperature of the fuel to prevent "waxing" and "gelling" of the fuel in the lines during cold weather operation. One type uses engine coolant as a heating source. In order for this type to heat the fuel, the engine must first be started and allowed to run until the coolant temperature increases. Though this type of heater will usually increase fuel mileage, it offers no aid in starting ability.

The other type of heater uses a 12V DC electric heating element. This type is recommended, due to its ability to warm the fuel BEFORE the engine is started. This type of heater will also usually increase the overall fuel mileage.

Installation

Follow the manufacturer's instructions exactly. Also, see suggestions 5, 8, and 9 under "Separator Installation".

CYLINDER BLOCK HEATERS

A cylinder block heater electrically (usually 110V house current) heats the engine coolant, which in turn warms the cylinder block, heads, and engine oil. In this case, the warmth is not used to alter the characteristics of the fuel. Block heaters offer two main advantages when starting a diesel in cold weather:

1. The reduced viscosity (thinning) of the engine oil from the warmth allows the engine to be "turned over" easier (and faster) by the starter. Less strain is imposed on the starting system.
2. Because the diesel relies on the heat of compression to ignite the fuel, the increase in the base combustion chamber temperature results in a higher temperature during compression. This allows the fuel to ignite easier than if just the glow plugs were used.

Installation

Most cylinder block heaters replace one of the existing freeze (or expansion) plugs of the cylinder block. Follow the manufacturers installation instructions exactly. Also, refer to the manufacturers recommendations for usage.

DOMESTIC CARBURETOR SERVICE

Carburetor Identification

All carburetors are identified by code numbers, either stamped on the attaching flange side, the main body or on a metal tag retained by a bowl cover screw. This identification number is important in order to obtain the correct carburetor replacement or parts and to properly adjust the carburetor when matched to a specific engine.

Special Tools

An angle degree tool is recommended by Rochester Products Division for use to confirm adjustments to the choke valve and related linkages on late model 2 and 4 barrel carburetors in place of the plug type gauges. Decimal and degree conversion charts are provided for use with the angle degree tool. To use the angle gauge, rotate the degree scale until zero (0) is opposite the pointer. With the choke valve completely closed, place the gauge magnet squarely on top of the choke valve and rotate the bubble until it is centered. Make the necessary adjustments to have the choke valve at the specified degree angle opening as read from the degree angle tool. The carburetor may be off the engine for adjustments, but make sure the carburetor is held firmly during the use of the angle gauge.

A variety of other special adjustment tools may be necessary during the overhaul of different carburetors covered in this section. Most carburetor overhaul kits contain the float level gauges and specifications necessary for complete rebuilding, and if specifications differ from those given in the following charts, use the values listed in the overhaul instructions with a specific kit. Before beginning any overhaul procedures, read through each section to make sure all required special tools are on hand in order to complete the repair.

Carburetor Overhaul Tips

When the carburetor is disassembled, wash all parts (except diaphragms, electric choke units, pump plunger, and any other plastic, leather, fiber, or

rubber parts) in clean carburetor solvent. Do not leave parts in the solvent any longer than is necessary to sufficiently loosen the deposits. Excessive cleaning may remove the special finish from the float bowl and choke valve bodies, leaving these parts unfit for service. Rinse all parts in clean solvent and blow them dry with compressed air or allow them to air dry. Wipe clean all cork, plastic, leather, and fiber parts with a clean, lint-free cloth.

Blow out all passages and jets with compressed air and be sure that there are no restrictions or blockages. Never use wire or similar tools to clean jets, fuel passages, or air bleeds. Clean all jets and valves separately to avoid acci-

dental interchange. Check all parts for wear or damage. If wear or damage is found, replace the defective parts. Especially check the following:

1. Check the float needle and seat for wear. If wear is found, replace the complete assembly.

2. Check the float hinge pin for wear and the float(s) for dents or distortion. Replace the float if fuel has leaked into it.

3. Check the throttle and choke shaft bores for wear or an out-of-round condition. Damage or wear to the throttle arm, shaft, or shaft bore will often require replacement of the throttle body. These parts require a close tolerance of fit. Wear may allow air leakage, which could affect starting and idling.

NOTE: Throttle shafts and bushings are not included in over-

haul kits. They can be purchased separately.

4. Inspect the idle mixture adjusting needles for burrs or grooves. Any such condition requires replacement of the needle, since you will not be able to obtain a satisfactory idle.

5. Test the accelerator pump check valves. They should pass air one way but not the other. Test for proper seating by blowing and sucking on the valve. Replace the valve if necessary. If the valve is satisfactory, wash the valve again to remove breath moisture.

6. Check the bowl cover for warped surfaces with a straight edge.

7. Closely inspect the valves and seats for wear and damage, replacing as necessary.

8. After the carburetor is assembled, check the choke valve for freedom of operation.

Carburetor overhaul kits are recommended for each overhaul. These kits contain all gaskets and new parts to replace those that deteriorate most rapidly. Failure to replace all parts supplied with the kit (especially gaskets) can result in poor performance later.

After cleaning and checking all components, reassemble the carburetor, using new parts and referring to the exploded view. When reassembling, make sure that all screws and jets are tight in their seats, but do not overtighten as the tips will be distorted. Tighten all screws gradually, in rotation. Do not tighten needle valves into their seats. Uneven jetting will result. Always use new gaskets. Be sure

to adjust the float level, following the instructions contained in the rebuilding kit, when reassembling.

GENERAL MOTORS

Rochester Carburetors

Refer to the individual truck section for idle speed and idle mixture adjustments, using the propane enrichment procedure on non-electronic controlled engine carburetors and with the use of a dwellmeter on the electronic controlled carburetor equipped engines.

Rochester M4MED and M4MEF carburetor exploded view — 1987-89

Rochester M4ME carburetor exploded view—1987 California models

1. REMOVE AIR HORN, GASKET, POWER PISTON AND METERING ROD ASSEMBLY, AND FLOAT BOWL INSERT.
2. ATTACH J-34817-1 OR BT-8227A-1 TO FLOAT BOWL.
3. PLACE J-34817-3 OR BT-8227A IN BASE WITH CONTACT PIN RESTING ON OUTER EDGE OF FLOAT LEVER.
4. MEASURE DISTANCE FROM TOP OF CASTING TO TOP OF FLOAT, AT POINT $\frac{3}{16}$ " FROM LARGE END OF FLOAT. USE J-9789-90 OR BT-8037.
5. IF MORE THAN $\pm \frac{2}{32}$ " FROM SPECIFICATION, USE J-34817-25 OR BT-8427 TO BEND LEVER UP OR DOWN. REMOVE BENDING TOOL AND MEASURE, REPEATING UNTIL WITHIN SPECIFICATION.
6. CHECK FLOAT ALIGNMENT.
7. REASSEMBLE CARBURETOR.

Rochester M4ME, M4MED and M4MEF float adjustment

Rochester M4ME, M4MED and M4MEF pump adjustment

Rochester M4ME, M4MED and M4MEF choke valve angle gauge usage

Rochester M4ME, M4MED and M4MEF air valve spring adjustment

- 1 ATTACH RUBBER BAND TO GREEN TANG OF INTERMEDIATE CHOKE SHAFT
- 2 OPEN THROTTLE TO ALLOW CHOKE VALVE TO CLOSE
- 3 SET UP ANGLE GAGE AND SET ANGLE TO SPECIFICATION
- 4 ON QUADRAJET, HOLD SECONDARY LOCKOUT LEVER AWAY FROM PIN
- 5 HOLD THROTTLE LEVER IN WIDE OPEN POSITION
- 6 ADJUST BY BENDING TANG OF FAST IDLE LEVER UNTIL BUBBLE IS CENTERED

Rochester M4ME, M4MED and M4MEF unloader adjustment

- 1 ATTACH RUBBER BAND TO GREEN TANG OF INTERMEDIATE CHOKE SHAFT.
- 2 OPEN THROTTLE TO ALLOW CHOKE VALVE TO CLOSE.
- 3 SET UP ANGLE GAGE AND SET ANGLE TO SPECIFICATION.
- 4 RETRACT VACUUM BREAK PLUNGER, USING VACUUM SOURCE, AT LEAST 18" HG. PLUG AIR BLEED HOLES WHERE APPLICABLE.
- 4A ON QUADRAJETS, AIR VALVE ROD MUST NOT RESTRICT PLUNGER FROM RETRACTING FULLY. IF NECESSARY, BEND ROD HERE TO PERMIT FULL PLUNGER TRAVEL. WHERE APPLICABLE, PLUNGER STEM MUST BE EXTENDED FULLY TO COMPRESS PLUNGER BUCKING SPRING.

Rochester M4ME, M4MED and M4MEF rear (secondary) vacuum break adjustment

PLUGGING AIR BLEED HOLES

BUCKING SPRINGS

Rochester M4ME, M4MED and M4MEF vacuum break inspection

Rochester M4ME, M4MED and M4MEF secondary lockout adjustment

Rochester M4ME, M4MED and M4MEF coil lever adjustment

Rochester M4ME, M4MED and M4MEF rear air valve rod adjustment—1986

23 CARBURETORS DOMESTIC

Rochester M4ME, M4MED and M4MEF rear air valve rod adjustment—1986

- ① Plug Vacuum Break bleed holes, if applicable. Air Valves (A) closed. Apply 15" Hg (51 k Pa) vacuum to seat Vacuum Break Plunger.
- ② Gage the clearance between Air Valve Link and end of slot in lever.
- ③ Adjust, if necessary, by bending link.

Rochester M4ME, M4MED and M4MEF air valve rod adjustment—1987-89

Rochester M4ME, M4MED and M4MEF choke rod fast idle cam adjustment

- ① ATTACH RUBBER BAND TO GREEN TANG OF INTERMEDIATE CHOKE SHAFT
- ② OPEN THROTTLE TO ALLOW CHOKE VALVE TO CLOSE
- ③ SET UP ANGLE GAGE AND SET TO SPECIFICATION
- ④ RETRACT VACUUM BREAK PLUNGER USING VACUUM SOURCE, AT LEAST 18" HG. PLUG AIR BLEED HOLES WHERE APPLICABLE

ON QUADRAJETS, AIR VALVE ROD MUST NOT RESTRICT PLUNGER FROM RETRACTING FULLY. IF NECESSARY, BEND ROD (SEE ARROW) TO PERMIT FULL PLUNGER TRAVEL. FINAL ROD CLEARANCE MUST BE SET AFTER VACUUM BREAK SETTING HAS BEEN MADE.

- ⑤ WITH AT LEAST 18" HG STILL APPLIED, ADJUST SCREW TO CENTER BUBBLE

Rochester M4ME, M4MED and M4MEF front (primary) vacuum break adjustment—1986

- ① Attach rubber band to Vacuum Break Lever of Intermediate Choke Shaft.
- ② Open Throttle to allow Choke Valve to close.
- ③ Set up Angle Gage and set to specification.
- ④ Plug Vacuum Break Bleed Holes, if applicable.

Apply 15" Hg (51 k Pa) vacuum to seat Vacuum Break Plunger.

Seat Bucking Spring (A), if applicable.

On Quadrajets, if necessary:

- Bend Air Valve Link (B) to permit full plunger travel.
- Reapply vacuum.

- ⑤ Adjust, if bubble is not recentered, by turning screw.

Rochester M4ME, M4MED and M4MEF front (primary) vacuum break adjustment—1987-89

TPS ADJUSTMENT SPECIFICATIONS General Motors Corporation

Year	Engine Code	TPS Voltage
1986	F	0.41
	L	0.41
	N	0.25

NOTE: Measure voltage with throttle at curb idle position, ignition ON, engine and A/C OFF. All values ± 0.1 volt.

FORD MOTOR
CARBURETORS
Emission Calibration
Numbers

Emission calibration numbers are

used by Ford Motor Company to provide the technician with the necessary specifications to adjust a specific engine to the proper emission control levels. The calibration numbers are listed on the lower right of the Vehicle Emission Control Information label, which is attached to the engine valve cover. The information on the decal must be used when differences exist between the decal and other specification tables, unless otherwise noted by Ford Motor Company.

Asian model Y carburetor—exploded view

JEEP

Carter Carburetors

MODEL BBD

Float Adjustment

1. Remove the air horn.
2. Apply light finger pressure to the vertical float tab to exert gentle pressure against the inlet needle.
3. Lay a straight edge across the float bowl and measure the gap between the straight edge and the top of the float at its highest point. The gap should be 0.250 in.
4. To adjust, remove the float and bend the lower tab. Replace the float and check the gap.

Fast Idle Cam Adjustment

1. Loosen the choke housing cover

and turn it $\frac{1}{4}$ turn right. Tighten one screw.

2. Slightly open the throttle and place the fast idle screw on the second cam step.

3. Measure the distance between the choke plate and the air horn wall. The distance should be 0.095 in.

4. If adjustment is necessary, bend the fast idle cam link down to increase and up to decrease the gap.

5. Return the choke cover cap to the original setting.

Initial Choke Valve Clearance

1. Position the fast idle screw on the top step of the fast idle cam.
2. Using a vacuum pump, seat the choke vacuum break.
3. Apply light closing pressure in the choke plate to position the plate as far closed as possible without forcing it.
4. Measure the distance between the air horn wall and the choke plate,

it should be 0.140 in. If it is not, bend the choke vacuum break link until it is.

Unloader Adjustment

1. With the throttle held fully open, apply pressure on the choke valve toward the closed position and measure the clearance between the lower edge of the choke valve and the air horn wall.

2. The measurement should be 0.280 in. Adjust by bending the tang on the throttle lever which contacts the fast idle cam. Bend toward the cam to increase the clearance.

NOTE: Do not bend the unloader down so that it binds or interferes with any other component.

Vacuum (Step Up) Piston Gap

1. Turn the adjusting screw, mounted on top of the unit, so that the gap between the metering rod lifter lower edge, and the top of the vacuum piston, is 0.035 in.

Carter BBD carburetor — exploded view

Carter BBD choke unloader adjustment

Carter BBD accelerator pump adjustment

2. Counting the number of turns involved, turn the curb idle adjustment screw counterclockwise, until the throttle valves are completely closed.

3. Fully depress the vacuum piston, while exerting moderate pressure on the metering rod lifter tab. In this position, tighten the rod lifter lock screw.

4. Release the piston and rod lifter.

NOTE: The accelerator pump should now be adjusted.

5. Return the curb idle adjustment screw to its original position.

Accelerator Pump

1. Counting the number of turns involved, turn the curb idle adjustment screw counterclockwise, until the throttle valves are completely closed.

2. Open the choke valve so that the fast idle cam will allow the throttle valves to seat in their bores.

3. Turn the curb idle adjustment screw clockwise, so that it just barely touches the stop, then, turn it 2 full turns further.

Carter BBD piston gap adjustment

4. Measure the distance between the surface of the air horn and the top of the accelerator pump shaft with a T-scale. The distance should be 0.520 in.

5. If the dimension is not correct,

loosen the pump arm adjusting screw and rotate the sleeve to adjust the pump travel. Tighten the lock screw.

6. Return the curb idle screw to its original position.

① Engine hot, EGR valve disconnected

MODEL YFA

Float Level Adjustment

1. Remove the top of the carburetor and the gasket.

2. Invert the carburetor top and check the clearance from the top of the float to the bottom edge of the air horn with a float level gauge. Hold the carburetor top at eye level when making the check. The float arm should be resting on the inlet needle pin. To adjust, bend the float arm.

NOTE: Do Not bend the tab at the end of the arm.

Fast Idle Cam Adjustment

1. Run the engine to normal operating temperature. Connect a tachometer.

2. Disconnect and plug the EGR valve vacuum hose.

3. Position the fast idle adjustment screw on the second stop of the fast idle cam with the transmission in neutral.

4. Adjust the fast idle speed to 2300 rpm for automatic transmission and 2000 rpm for manual transmission.

5. Idle the engine and reconnect the EGR hose.

Initial Choke Valve Clearance

1. Position the fast idle screw on the top step of the fast idle cam.

2. Using a vacuum pump, seat the choke vacuum break.

3. Apply light closing pressure in the choke plate to position the plate as far closed as possible without forcing it.

4. Measure the distance between the air horn wall and the choke plate, it should be 0.280 in. If it is not, bend the choke vacuum break link until it is.

② Measured between choke valve and air horn fast idle screw on 2nd cam step

Motorcraft Carburetors

MODEL 2150

Dry Float Adjustment

1. With the air horn assembly and the gasket removed raise the float by pressing down on the float tab until the fuel inlet needle is lightly seated.
2. Using a T-scale, measure the distance from the fuel bowl machined surface to either corner of the float $\frac{1}{8}$ in. (3mm) from the free end.
3. To adjust bend the float tab and hold the fuel inlet needle off its seat in order to prevent damage to the seat and the tip of the needle.

Motorcraft 2150 dry float level adjustment

Wet Float Adjustment

CAUTION

Exercise extreme care when performing this adjustment as fuel vapors and liquid fuel are present and could cause personal injury if ignited.

1. Place the vehicle on a flat, level surface and run the engine to normal operating temperature. Turn off the engine and remove the air cleaner.
2. Remove the air horn attaching screws, but leave the air horn in place.
3. Start the engine and let it idle for one minute. Shut off the engine and remove the air horn and gasket.
4. Use a T-scale to measure the vertical distance between the machined surface of the carburetor body and the fuel level in the bowl. Make this measurement as near the center of the bowl as possible. The proper distance is $\frac{1}{4}$ in. To adjust, bend the float tab.

Motorcraft 2150 wet float level adjustment

Motorcraft 2150 carburetor—exploded view

Fast Idle Cam Adjustment

1. Push down on the fast idle cam lever until the fast idle speed adjusting screw is contacting the second step (index), and against the shoulder of the high step.

2. Measure the clearance between the lower edge of the choke valve and air horn wall.

3. Adjust by turning the fast idle cam lever screw to obtain the proper specification.

Initial Choke Valve Clearance

1. Remove the choke cover shield.

2. Loosen the choke cover coil retaining screws. If rivets are used grind away and replace with screws.

NOTE: Every time an adjustment is made, the air horn must be replaced, and the engine started and idled for one minute to stabilize the fuel level.

5. Install the air horn and gasket when adjustment is completed.

Motorcraft 2150 fast idle cam adjustment

Motorcraft 2150 initial choke valve clearance adjustment

- 3. Open the throttle and rotate the choke cover until the choke valve is held close.
- 4. Tighten 1 cover retaining screw.
- 5. Close the throttle with the fast idle screw adjustment screw on the top step of the cam.
- 6. Use a hand held vacuum pump and apply vacuum to hold the choke diaphragm against the setscrew.
- 7. Measure the clearance between the lower edge of the choke valve and the top of the air horn.
- 8. Adjust the clearance by turning the screw at the rear of the choke vacuum diaphragm.
- 9. Make a fast idle cam adjustment.

Choke Setting

The automatic choke setting is made by loosening the choke cover in the desired direction as indicated by an arrow on the face of the cover. the original setting will be satisfactory for most driving conditions. However, if the engine stumbles or stalls on acceleration during warmup, the choke may be set richer or leaner no more than two graduations from the original setting.

Unloader Adjustment

- 1. With the throttle held fully open, apply pressure on the choke valve toward the closed position and measure the clearance between the lower edge

- of the choke valve and the air horn wall.
- 2. Adjust by bending the tang on the throttle lever which contacts the fast idle cam. Bend toward the cam to increase the clearance.
- NOTE: Do not bend the unloader down so that it binds or interferes with any other component.**
- 3. A clearance of 0.070 in. (1.8mm) must be between the unloader tang and the edge of the fast idle cam. Final unloader adjustment must always be done on the vehicle. The throttle should be fully opened by depressing the accelerator pedal to the floor. This is to assure that full throttle is obtained.

Rochester Carburetors

MODELS 2SE/E2SE

Float and Fuel Level Adjustment

1. Start the engine and run it to normal operating temperature.
2. Remove the vent stack screws and the vent stack.
3. Remove the air horn screw adjacent to the vent stack.
4. With the engine idling and the choke fully opened, carefully insert float gauge J-9789-136 for E2SE carburetors and tool J-9789-138 for 2SE carburetors, into the air horn screw hole and vent hole. Allow the gauge to rest freely on the float.

NOTE: Do not press down on the float.

5. With the gauge at eye level, observe the mark that aligns with the top of the casting at the vent hole. The float level should be within 0.06 in. (1.5mm) of the specifications. If not, remove the air horn and adjust the float as follows:
 - a. Hold the retainer pin firmly in place and push the float down, lightly, against the inlet needle.
 - b. Using an adjustable T-scale, at a point $\frac{3}{16}$ in. (5mm) from the end of the float, at the toe, measure the distance from the float bowl top surface (gasket removed) to the top of the float at the toe. If not within specification, remove the float and bend the arm.

Fast Idle Cam Adjustment

1. Make sure the choke coil adjustment is correct and that the fast idle speed is correct.
2. Obtain a choke angle gauge, tool No. J-26701-A. Rotate the degree scale to the zero degree mark opposite the pointer.

Rochester 2SE and E2SE float level measurement

Rochester 2SE and E2SE float level adjustment

Rochester 2SE and E2SE carburetor—exploded view

3. With the choke valve completely closed, place the magnet on the tool squarely on the choke plate. Rotate the bubble unit until it is centered.

4. Rotate the degree scale until the 22 degree mark is opposite the pointer.

5. Place the fast idle screw on the second step of the cam.

6. Close the choke plate by pushing on the intermediate choke lever.

7. Push the vacuum brake lever toward the open choke position until the lever is against the rear tank on the choke lever.

8. Adjust by bending the fast idle cam rod until the bubble is centered.

Choke Coil Lever Adjustment

NOTE: Once the rivets and choke cover are removed, a choke cover retainer kit is necessary for assembly.

1. Remove the rivets, retainers, choke cover and coil following the instructions found in the cover retainer kit.

2. Position the fast idle adjustment screw on the highest stop of the fast idle cam.

3. Push on the intermediate choke lever and close the choke plate.

4. Insert a 0.85 in. plug gauge, in the hole adjacent to the coil lever. The edge of the lever should barely contact the plug gauge.

5. Bend the intermediate choke rod to adjust.

Unloader Adjustment

1. Obtain a carburetor choke angle gauge, tool No. J-26701-A. Rotate the scale on the gauge until the 0 mark is opposite the pointer.

2. Close the choke plate completely and set the magnet squarely on top of it.

3. Rotate the bubble until it is centered.

4. Rotate the degree scale until the 40° mark is opposite the pointer.

5. Hold the primary throttle valve wide open.

6. Bend the throttle lever tang until the bubble is centered.

Primary Vacuum Break Adjustment

1. Obtain a carburetor choke angle gauge, tool No. J-26701-A. Rotate the scale on the gauge until the 0 mark is opposite the pointer.

2. Rotate the degree scale until the correct specification mark is opposite the pointer.

3. Place tape over the vacuum bleed in the diaphragm.

4. Set the choke vacuum diaphragm using a hand vacuum pump.

Rochester 2SE and E2SE fast idle cam adjustment

Rochester 2SE and E2SE choke coil lever adjustment

Rochester 2SE and E2SE choke unloader adjustment

5. Hold the choke valve at its closed position by pushing on the choke lever.
6. Adjust to the proper specification by bending the primary vacuum break rod.

Secondary Vacuum Break Adjustment

1. Obtain a carburetor choke angle gauge, tool No. J-26701-A. Rotate the scale on the gauge until the 0 mark is opposite the pointer.
2. Rotate the degree scale until the correct specification mark is opposite the pointer.
3. Place tape over the vacuum bleed in the diaphragm.
4. Seat the choke vacuum diaphragm using a hand vacuum pump.
5. Hold the choke valve at its closed position by pushing on the choke lever.
6. Adjust to the proper specification by bending the secondary vacuum break rod.

Rochester 2SE and E2SE primary vacuum break adjustment

Rochester 2SE and E2SE secondary vacuum break adjustment

Air Valve Spring Adjustment

1. If necessary, remove the intermediate choke rod to gain access to the lock screw. Loosen the lock screw.
2. Turn the tension adjusting screw clockwise until the air valve opens slightly.
3. Turn the adjusting screw counterclockwise until the air valve just closes.

Continue counterclockwise to the specified number of turns.

4. Tighten the lock screw.

Air Valve Rod Adjustment

1. Obtain a carburetor choke angle gauge, tool No. J-26701-A. Rotate the scale on the gauge until the 0 mark is opposite the pointer.
2. Rotate the degree scale until the correct specification mark is opposite the pointer.
3. Seat the choke vacuum diaphragm using a hand vacuum pump.
4. Place tape over the vacuum bleed in the diaphragm.
5. Apply light pressure to the air valve shaft in the direction to open the valve to ensure all slack is removed between the air valve link and the plunger slot.
6. Bend the air valve link with tool J-97789-111 until the bubble is centered.

Rochester 2SE and E2SE air valve spring adjustment adjustment

Rochester 2SE and E2SE air valve link adjustment adjustment

IMPORT CARBURETOR SERVICE

Carburetor Identification

All carburetors are identified by code numbers, either stamped on the attaching flange side, the main body or on a metal tag retained by a bowl cover screw. This identification number is important in order to obtain the correct carburetor replacement or parts and to properly adjust the carburetor when matched to a specific engine.

Carburetor Overhaul Tips

When the carburetor is disassembled, wash all parts (except diaphragms, electric choke units, pump plunger, and any other plastic, leather, fiber, or rubber parts) in clean carburetor solvent. Do not leave parts in the solvent any longer than is necessary to sufficiently loosen the deposits. Excessive cleaning may remove the special finish from the float bowl and choke valve bodies, leaving these parts unfit for service. Rinse all parts in clean solvent and blow them dry with compressed air or allow them to air dry. Wipe clean all cork, plastic, leather, and fiber parts with a clean, lint-free cloth.

Blow out all passages and jets with compressed air and be sure that there

are no restrictions or blockages. Never use wire or similar tools to clean jets, fuel passages, or air bleeds. Clean all jets and valves separately to avoid accidental interchange. Check all parts for wear or damage. If wear or damage is found, replace the defective parts. Especially check the following:

1. Check the float needle and seat for wear. If wear is found, replace the complete assembly.

2. Check the float hinge pin for wear and the float(s) for dents or distortion. Replace the float if fuel has leaked into it.

3. Check the throttle and choke shaft bores for wear or an out-of-round condition. Damage or wear to the throttle arm, shaft, or shaft bore will often require replacement of the throttle body. These parts require a close tolerance of fit. Wear may allow air leakage, which could affect starting and idling.

4. Inspect the idle mixture adjusting needles for burrs or grooves. Any such condition requires replacement of the needle, since you will not be able to obtain a satisfactory idle.

5. Test the accelerator pump check valves. They should pass air one way but not the other. Test for proper seating by blowing and sucking on the valve. Replace the valve if necessary. If the valve is satisfactory, wash the valve again to remove breath moisture.

6. Check the bowl cover for warped surfaces with a straight edge.

7. Closely inspect the valves and seats for wear and damage, replacing as necessary.

8. After the carburetor is assembled, check the choke valve for freedom of operation.

Carburetor overhaul kits are recommended for each overhaul. These kits contain all gaskets and new parts to replace those that deteriorate most rapidly. Failure to replace all parts supplied with the kit (especially gaskets) can result in poor performance later.

After cleaning and checking all components, reassemble the carburetor, using new parts and referring to the exploded view. When reassembling, make sure that all screws and jets are tight in their seats, but do not overtighten as the tips will be distorted. Tighten all screws gradually, in rotation. Do not tighten needle valves into their seats. Uneven jetting will result. Always use new gaskets. Be sure to adjust the float level, following the instructions contained in the rebuilding kit, when reassembling.

CHRYSLER IMPORTS AND MITSUBISHI

Float Level Adjustment

1. Invert the float chamber cover assembly without a gasket.

2. Position a float gauge and measure the distance from the bottom of the float to the surface of the float chamber cover.

3. If not within specification the shim under the needle seat must be changed.

Chrysler/Mitsubishi carburetor upper half exploded view

Chrysler/Mitsubishi carburetor lower half exploded view

Chrysler/Mitsubishi float level adjustment

Chrysler/Mitsubishi fast idle opening adjustment

Chrysler/Mitsubishi choke breaker opening measurement

4. Adding or removing a shim will change the float level by 3 times the thickness of the shim.

Fast Idle Opening Adjustment

1986

1. With the carburetor at room temperature, insert the diameter drill specified and adjust the fast idle opening by adjusting the fast idle screw.

2. Use a drill diameter of 0.028 in. on vehicles with manual transmission and 0.031 in. with automatic transmission.

Choke Breaker Opening

1. Disconnect the vacuum hose (yellow stripe) from the choke breaker.

2. With the engine idling, close the choke valve lightly until the choke valve stops.

3. Measure the choke valve to choke bore clearance to see if it is within the 1st stage specification. If necessary,

remove the bimetal assembly and adjust the rod end opening to be within the 1st stage specification.

NOTE: When removing the bimetal assembly, put a mark on the electric choke body.

4. Reconnect the vacuum hose (yellow stripe) from the choke breaker and remeasure the choke valve to choke bore clearance.

5. If the clearance is not within the 2nd stage specification, adjust by the adjusting screw.

Throttle Position Sensor Adjustment

1986

1. Warm the engine to normal operating temperature and make sure the fast idle cam is released.

2. Stop the engine, then turn the No. 1 and 2 idle speed adjusting screws counterclockwise enough to close the throttle valve completely. Record the number of turns.

3. Connect a digital type voltmeter between the TPS connectors 2 and 3.

NOTE: Do not disconnect the TPS connector and body harness.

4. Switch the ignition key on and adjust the TPS-adjustment screw so that the TPS output is 0.25 volts.

5. Turn the ignition key off.

6. Close the No. 1 and 2 idle speed adjusting screws the same number of turns.

1987-89

Montero and Pick-up

1. Loosen the accelerator cable.

2. Turn the No. 1 and 2 idle speed adjusting screws counterclockwise enough to close the throttle valve completely. Record the number of turns. At this time, the fast idle control should have been released (the lever not resting on the fast idle cam).

3. Disconnect the carburetor connectors.

4. Connect the special test harness tool MD998474 between the disconnected connectors.

5. Connect a digital voltmeter between the No. 2 red sensor output terminal and the No. 8 blue sensor (ground) of the carburetors connectors.

6. Turn the ignition switch to ON but do not start the engine.

7. Measure the output voltage of the TPS. The standard value is 0.25 volts.

8. If adjustment is necessary, loosen the TPS attaching screw and adjust by turning the TPS to the standard value.

Chrysler/Mitsubishi TPS adjusting screw - 1986

Chrysler/Mitsubishi No. 1 and No. 2 idle speed adjusting screws - 1987-89

Chrysler/Mitsubishi fast idle cam and lever - 1987-89

Chrysler/Mitsubishi TPS adjustment - 1987-89

NOTE: Turning the TPS clockwise increases the output voltage.

9. Tighten the No. 1 and 2 idle speed adjusting screws recorded earlier.

10. Remove the voltmeter and the special tool and connect the carburetor's connector.

11. Adjust the play of the accelerator cable.
12. Check that the idle speed is as specified on the Emission Control Label.

Ram 50 and Ram Raider

1. Loosen the accelerator cable.
2. Turn the No. 1 and 2 idle speed adjusting screws counterclockwise enough to close the throttle valve completely. Record the number of turns. At this time, the fast idle control should have been released (the lever not resting on the fast idle cam).
3. Turn the ignition switch to **LOCK**.
4. Disconnect the large and small harness connector from the engine control unit.
5. Set the check switch of the ECI switch **OFF**.
6. Set the select switch of the ECI checker tool MD998451 to **A**.
7. Connect a carburetor test harness MD998456 to the engine control unit and the harness connectors.
8. Connect a volt meter to the extension terminals of the ECI checker, and then change the extension switch from **CHECK METER** down to the extension position.
9. Set the select switch and the check switch on the ECI checker to **A** and **3** respectively.
10. Turn the ignition switch to **ON** but do not start the engine.
11. Measure the output voltage of the TPS. The standard value is 0.25 volts.
12. If adjustment is necessary, loosen the TPS attaching screw and adjust by turning the TPS to the standard value.

NOTE: Turning the TPS clockwise increases the output voltage.

13. Set the check switch of the ECI checker to **OFF**.
14. Set the ignition switch to **LOCK**.
15. Disconnect the connectors of the ECI checker and the carburetor test harness from the engine control unit and body side harness connectors.
16. Connect the body side harness connectors to the engine control unit.
17. Tighten the No. 1 and No. 2 idle speed adjusting screws recorded earlier.
18. Adjust the play of the accelerator cable.
19. Check that the idle speed is as specified on the emission control label.

Dashpot Adjustment

1. Make sure the curb idle speed is correct, the engine temperature is at normal operating temperature, lights and accessories off, manual transmis-

Chrysler/Mitsubishi No. 2 and No. 3 idle speed adjustment screws—1987-89

sion in neutral and automatic transmission in **PARK**.

2. Start the engine and run at idle.
3. Close the throttle valve until the No. 2 idle speed adjusting screw contacts the free lever. Check the engine speed at that moment. If the engine speed is not as specified, adjust the dashpot by turning the No. 3 idle speed adjustment screw.
4. Release the free lever and verify that the engine returns to the idle speed slowly.

ISUZU

Stromberg Carburetor

Float Level Adjustment

1986-90

The fuel level is normal if it is within the mark on the window. If the level is outside the line, adjust by bending the float seat. The needle valve should have an effective stroke of about 0.059 in. The float stroke may be measured as follows:

1. Hold the carburetor with the bottom side up and fully raise the float.
2. Measure the distance between the valve stem (resting at its bottom position) and the float seat.
3. Normal clearance is 0.059 in. Bend the float stopper as necessary to adjust.

Primary Throttle Valve Adjustment

1986-87

The primary throttle valve is opened by means of the fast idle adjusting screw to an angle of 16 degrees when the choke valve is completely closed. The primary throttle valve opening angle may be checked as follows:

1. Close the choke valve completely and measure the clearance between the center of the throttle valve and the wall of the throttle valve chamber. Standard clearance is 0.050-0.059 in.

2. Adjust the throttle valve opening angle with the fast idle adjusting screw.

NOTE: Be sure to turn the throttle stop screw all the way in before measuring the clearance.

Kick Lever Adjustment

1986-87

1. Turn out the throttle valve adjusting screw to completely close the primary side of the throttle valve.
2. Loosen the locknut on the kick lever screw and turn the screw until it is in contact with the return plate.
3. Tighten the locknut.

Isuzu (Stromberg) carburetor disassembled view of the choke chamber and float chamber — 1988-90

Isuzu (Stromberg) choke valve opening — 1988-90

Choke Valve Opening Adjustment

1988-90

1. Move the fast idle screw tip against the 2nd step of the fast idle cam.

Isuzu (Stromberg) unloader adjustment — 1988-90

2. Measure the clearance between the choke valve and the choke valve chamber wall.

3. If the clearance measured is not between 0.031-0.050 in., bend the counter lever tang to adjust.

Isuzu (Stromberg) primary and secondary throttle valve adjustment — 1988-90

Unloader Adjustment

1988-90

1. Open the primary valve fully.
2. Measure the clearance between the choke valve and the choke valve chamber wall.

3. If the clearance measured is not between 0.105-0.129 in., bend the adjusting lever tang to adjust.

Primary and Secondary Throttle Valve Adjustment

1988-90

1. Slowly open the primary throttle valve until the kick lever tang contacts the return plate.

2. Measure the clearance between the choke valve and the choke valve chamber wall.

3. If the clearance measured is not between 0.272-0.331 in., bend the kick lever tang to adjust.

MAZDA

Float Level Adjustments

B2000 AND B2200

1. Without the gasket turn the air horn upside down and allow the float to lower by its own weight.

2. Measure the clearance between the float and the air horn.

3. Bend the float seat lip until the proper clearance is obtained.

4. Turn the air horn to its normal position and allow the float to lower by its own weight.

5. Measure the clearance between the bottom of the float and the air horn. If the clearance is not between 1.811-1.850 in., bend the float stopper to adjust.

B2600

1. Invert the float chamber cover assembly.

Mazda float level adjustment with the air horn at its normal position—B2000 and B2200

Mazda float level measurement—B2600

Mazda valve seat shim location—B2600

Mazda float and pin—B2600

2. Measure the clearance between the bottom of the float to the surface of the float chamber cover without the gasket in place.

3. Add or remove needle valve seat shims to adjust the fuel level to specifications as follows:

- Pull out the float lever pin and remove the float.
- Remove the needle valve and retainer.
- Use pliers and remove the needle valve seat.
- Insert the necessary shims for adjustment and reinstall the needle valve, float and float chamber cover.

Mazda carburetor disassembled view—B2000 and B2200

Mazda float needle valve seat and retainer—B2600

Mazda choke diaphragm adjustment—B2000 and B2200

Mazda fast idle cam adjustment—B2000 and B2200

Choke Diaphragm Adjustment B2000 AND B2200

1. Using a vacuum pump, apply a vacuum of about 15.7 in.Hg to the choke diaphragm vacuum tube.

2. Push the choke valve lightly to close it and measure the clearance.

3. If the clearance is not within

specification, adjust by bending the choke lever.

Fast Idle Cam Adjustment B2000 AND B2200

1. Set the fast idle cam to the second position.

2. Adjust the throttle valve clearance by turning the adjusting screw.

NOTE: The clearance will become larger as the screw is turned clockwise.

Mazda carburetor disassembled view — B2600

Fast Idle Opening Adjustment B2600

1. With the carburetor at normal room temperature, insert the specified drill between the choke valve and the choke valve chamber wall.
2. Adjust the fast idle opening by using the fast idle adjusting screw.

Choke Valve Clearance Adjustment B2000 AND B2200

1. Set the fast idle cam select to the second position.
2. Make sure the choke valve clearance is within specification.

Mazda fast idle opening adjustment — B2600

Mazda choke valve clearance adjustment — B2000 and B2200

3. Adjust the choke valve clearance by bending the starting arm. If a large adjustment is required, bend the choke rod.

Choke Valve Setting Adjustment B2500

1. Remove the choke cover. It may be necessary to grind off the rivet heads and replace with locking screws.
2. Remove the 2 lock screws and remove the choke valve pinion assembly.
3. Install the strangler spring to the choke lever.
4. Assemble, aligning the inscribed line or black painted line on the teeth of the choke pinion with the inscribed line on the cam lever.
5. Loosely tighten the new lock screws.
6. Set the choke valve by moving the pinion arm up or down, align the punch mark on the float chamber cover with the center of the 3 inscribed lines and secure the pinion arm with the lock screws.

Dashpot Adjustment B2500

1. Warm the engine to normal operating temperature.
2. Connect a tachometer to the engine.

Fit the strangler spring to the choke lever—Mazda B2600

Aligning the cam lever and choke pinion—Mazda B2600

Pinion arm lock screws—Mazda B2600

Align the center line with the punch mark—Mazda B2600

Mazda secondary throttle valve adjustment—B2000 and B2200

Mazda dashpot adjustment—B2000 and B2200

Mazda unloader adjustment—B2000 and B2200

3. Push the dashpot rod up and loosen the dashpot adjusting screw.
4. Turn the adjusting screw clockwise and set the engine speed to specification.

Unloader Adjustment B2000 AND B2200

1. Open the primary throttle valve all the way.
2. Measure the choke valve clearance and if not within specification adjust by bending the tab.

Secondary Throttle Valve Adjustment

B2000 AND B2200

1. The secondary throttle valve should start to open when the primary throttle valve opens (50–52 degrees), and should be completely open at the same time that the primary throttle valve is fully open.
2. Check the clearance between the primary throttle valve and the wall of the throttle bore when the secondary throttle valve starts to open.
3. If the clearance is not within specification, bend the tab to adjust.

SUZUKI

Float Adjustment

The fuel level in the float chamber should be within the round mark at the center of the level gauge. If the level is not found within the round mark adjust as follows:

1. Remove the air horn and invert it.
2. To find the float level, measure the distance between the float and the mating surface of the air horn without the gasket.
3. If the float level is not to specification, bend the tongue up or down to adjust.
4. Check the float height with the float weight applied to the needle valve. Use a gauge such as a drill or bolt that is the correct thickness and bend the tongue to adjust.

Choke Valve Clearance Adjustment

1. Check the choke valve for smooth movement.
2. Make sure that the choke valve is closed almost completely when ambient temperature is below 77°F and the engine is cold.
3. Measure the clearance between the choke valve and the carburetor bore.
4. If the clearance is found excessively large or small, check the strangler spring, choke piston and each link

Suzuki (Sidekick) carburetor exploded view

in the choke system for smooth operation. Lubricate as necessary.

5. If clearance is still out of specification, remove the carburetor from the intake manifold and remove the idle up actuator from the carburetor.

6. Turn the fast idle cam counter-clockwise and insert a pin into the holes in the cam and bracket to lock the cam.

7. Using pliers, bend the choke lever up or down. Bending up causes the choke valve to close and down to open.

8. Start the engine and warm it up fully.

9. Stop the engine and check to see if the choke valve is fully open.

10. If the choke valve doesn't open fully, the wax element or its link system is defective. Replace defective parts as necessary.

Choke Piston Adjustment

1. Disconnect the choke piston hose at the throttle chamber.

2. While pushing down lightly on the choke valve to its closed position, apply vacuum to the choke piston hose with a vacuum gauge and measure the choke valve to carburetor bore clearance. It should be 0.04–0.05 in. for the Samurai and 0.070–0.078 in. for the Sidekick.

3. With vacuum applied, use a suitable tool and move the choke piston rod in towards the choke piston and check to see if the choke valve to carburetor bore clearance is 0.13–0.14 in. for the Samurai and 0.142–0.163 in. on the Sidekick.

Fast Idle Cam Adjustment

1. Make sure the ambient temperature is between 71–81°F and that the mark on the cam and the center of the cam follower are in alignment.

2. Disconnect the vacuum hose from the Three Way Solenoid Valve (TWSV) on the Samurai, or the Vacuum Switching Valve (VSV) on the

Sidekick and connect a vacuum pump gauge to its hose.

3. While applying 15 in.Hg of vacuum to the actuator, check the clearance between the actuator rod and the idle up adjusting screw.

4. Adjust as needed using the fast idle adjusting screw.

1. VSV
2. Vacuum hose
3. Idle up actuator
4. Actuator rod
5. Idle up adjusting screw

1. Choke piston
2. Choke valve shaft
3. Strangler spring

Suzuki choke lever adjusting tab

2. Fully open the throttle valve and measure the choke valve to carburetor bore clearance.

3. If necessary, bend the unloader arm to adjust.

TOYOTA

Fuel Level

The fuel level is about even with the center of the sight glass.

Float Level Adjustment

1. Allow the float to hang down by its own weight.

2. Measure the clearance between the float top and the air horn without the gasket.

3. The float level (raised position), should be 0.386 in. If necessary, bend the upper portion of the float tab to adjust to specification.

4. Lift up the float and measure the distance between the air horn and the float bottom.

5. The float level (lowered position), should be 0.189 in. If necessary, bend the lower portion of the float tab to adjust to specification.

Throttle Valve Opening (Angle) Adjustment

1. Measure the full opening angle of the of the primary and secondary throttle valves.

2. Both the primary and secondary

TOYOTA CARBURETORS

(All measurements in inches or degrees)

Year	Carburetor Number	Float Level	Throttle Valve Angle	Secondary Touch Angle	Fast Idle Angle	Choke Unloader Angle	Idle-Up Angle
1986-88	All	②	90°	59°	23°	45°	16.5°
1989	All	②	90°	59°	①	45°	16.5°

NOTE: Use angle degree tool for angle specifications

① Federal and Canada: 24.5 degrees

California: 23.0 degrees

② Raised position: 0.386 in.

Lowered position: 1.89 in.

throttle valve openings should be 90 degrees from the horizontal plane.

3. Adjust by bending the respective throttle arm levers of either valve.

Secondary Throttle Angle Measurement

1. Measure the primary throttle valve opening at the same time the second throttle valve just starts to open.

2. The standard angle is 59 degrees from the horizontal plane.

3. Adjustment is not necessary, this is a rebuilding reference only.

Fast Idle Angle Adjustment

1. Set the throttle shaft lever to the first step of the fast idle cam.

2. Measure the primary throttle valve angle with the choke valve fully closed.

3. Adjust by turning the fast idle adjusting screw.

Choke Unloader Adjustment

1. Measure the choke valve angle with the primary throttle valve fully opened.

2. Adjust by bending the primary throttle arm.

Idle-Up Angle Adjustment

1. Apply vacuum to the idle-up diaphragm.

2. Measure the throttle valve opening angle.

3. Adjust the angle by turning the idle adjusting screw.

Toyota carburetor exploded view

23 CARBURETORS IMPORT

Dashpot Adjustment

1. Open the throttle valve until the throttle lever separates from the dashpot end.

2. Release the throttle valve gradually, and check the dashpot touch angle when the throttle lever touches the dashpot end.

3. If the dashpot touch angle is not 24.5 degrees from the horizontal plane, unlock the locknut and adjust the angle by turning the dashpot diaphragm.

FRONT END TROUBLE DIAGNOSIS

Condition	Cause	Correction
Hard steering	1) Steering linkage needs lubrication 2) Low or uneven front tire pressure 3) Incorrect front wheel alignment (manual steering)	1) Lubricate the linkage 2) Inflate tires to the recommended pressure 3) Check and align the front suspension
Poor directional stability	1) Steering linkage need lubrication 2) Low or uneven tire pressure 3) Loose wheel bearings 4) Incorrect front wheel alignment (caster) 5) Broken springs 6) Malfunctioning shock absorber 7) Broken stabilizer bar or a missing link	1) Lubricate the linkage 2) Inflate tires to the recommended pressure 3) Adjust or replace the wheel bearings 4) Check and align the front suspension 5) Replace the springs 6) Check and replace the shock absorber 7) Replace the stabilizer bar or link
Front wheel shimmy (smooth road shake)	1) Tire and wheel are out of balance or out of round 2) Worn or loose wheel bearings 3) Worn ball joints 4) Malfunctioning shock absorber	1) Balance the tires, check run-out 2) Adjust the wheel bearings 3) Replace the ball joints 4) Check and replace the shock absorber
Vehicle pulls to one side (no braking action)	1) Low or uneven tire pressure 2) Front or rear brakes dragging 3) Broken or sagging front spring 4) Incorrect front wheel alignment (camber)	1) Inflate the tires to the recommended pressure 2) Adjust the brakes 3) Replace the spring 4) Check and align the front suspension
Noise in the front end	1) Steering linkage needs lubrication 2) Loose shock absorber or worn bushings 3) Worn control arm bushings 4) Worn or loose wheel bearings 5) Loose stabilizer bar 6) Loose wheel nuts 7) Spring is improperly positioned 8) Loose suspension bolts	1) Lubricate at the recommended intervals 2) Tighten the bolts or replace the shock absorber 3) Replace the bushings or control arm 4) Adjust or replace the wheel bearings 5) Tighten all the stabilizer bar attachments 6) Tighten the wheel nuts 7) Reposition the spring 8) Tighten to specifications or replace
Wheel tramp	1) Tire and the wheel are out of balance 2) Tire and the wheel are out of round 3) Blister or bump on the tire 4) Improper shock absorber action	1) Balance the wheels 2) Replace the tire 3) Replace the tire 4) Replace the shock absorber
Excessive or uneven tire wear	1) Underinflated or overinflated tires 2) Improper toe-in 3) Wheels are out of balance 4) Hard driving 5) Overloading the vehicle	1) Inflate the tire to the recommended pressure 2) Adjust toe-in setting 3) Balance the wheels 4) Follow proper driving techniques 5) Do not exceed the maximum recommended payload rating
Scuffed tires	1) Toe-in is incorrect 2) Excessive speed on turns 3) Tires are improperly inflated 4) Suspension arm is bent or twisted	1) Adjust toe-in setting 2) Follow proper driving techniques 3) Inflate the tires to the recommended pressure 4) Replace the suspension arm
Noisy shocks	1) Loose mounting	1) Check all mounting torques (bolt and/or nut)
Excessive road shock	1) Tire air pressure is too high 2) Loose wheel bearings	1) Deflate to correct pressure 2) Adjust bearings

FRONT END TROUBLE DIAGNOSIS

Condition	Cause	Correction
Excessive road shock	3) Camber adjustment is incorrect (negative camber contributes to road shock) 4) Weak or broken front spring 5) Loose suspension components	3) Adjust camber 4) Replace the spring 5) Inspect, repair, and adjust as necessary
Leaky shocks	1) Seals are worn out	1) Replace shocks
Weak shocks	1) Shocks are worn out 2) Loss of shock fluid	1) Replace shocks 2) Replace shocks
Vibration and shimmy	1) Seal damage resulting in loss of lubricant, corrosion, excessive wear 2) Tires and wheels, or brake drums, are out of balance 3) Bent wheel or tire is out of round 4) Wheel stud nuts torqued unevenly 5) Loose steering linkage 6) Wheel is loose on the hub 7) Driveline universal joints are rough or defective (may be confused with steering vibration) 8) Malfunctioning shock absorbers	1) Replace damaged parts as necessary 2) Balance the tires and wheels, turn the brake drums 3) Replace the wheel and remount, or replace the tire 4) Retorque the wheel stud nuts 5) Adjust, torque or repair as necessary 6) Inspect the wheel bolt for damage Replace the wheel if needed. Replace all wheel studs 7) Repair driveline 8) Replace the shock absorbers
Cupped tires	1) Front shock absorbers are defective 2) Worn ball joints 3) Wheel bearings are incorrectly adjusted or worn 4) Wheel and tire is out of balance 5) Excessive tire or wheel runout	1) Replace the shock absorbers 2) Replace the ball joints 3) Adjust or replace the wheel bearings (also replace the races) 4) Balance the wheel and tire 5) Check and compensate for runout

GENERAL INFORMATION

Wheel Alignment

For a vehicle to have safe steering control with a minimum of tire wear, certain established rules must be followed. These rules fix the values of planes, angles and radii relative to each other and to vehicle and tire dimensions. Some factors are built in, with no provision for adjustment; others are adjustable within limits. The entire system depends upon all value factors, separately and combined. It is therefore difficult to change some of the established settings without influencing others.

This system is called steering geometry or wheel alignment and requires a complete check of all the factors involved. Definitions of these factors and the effect each has on the vehicle are as follows.

Steering Wheel Position

Always check steering wheel alignment in conjunction with and at the same time as toe-in. In fact, the steering wheel spoke position, with the vehicle on a straight section of highway, may be the first indication of front end misalignment.

If the vehicle has been wrecked, or indicates any evidence of steering gear or linkage disturbance, the pitman arm should be disconnected from the sector shaft. The steering wheel (or gear) should be turned from extreme right to extreme left to determine the halfway point in its turning scope. This will be the spot on the gear that is in action during straight ahead driving and in which position the steering gear should be adjusted. With the steering wheel in the straight ahead position and the steering gear adjusted to zero lash status, reconnect the pitman arm.

CAMBER ANGLE

Camber is the amount that the front wheels are inclined outward or inward at the top. Camber is spoken of, and

measured, in degrees from the perpendicular. The purpose of the camber angle is to take some of the load off the spindle outboard bearing.

CASTER ANGLE

Caster is the amount that the king pin (or in the case of vehicles without king pins, the knuckle support pivots) is tilted towards the back or front of the vehicle. Caster is usually spoken of, and measured, in degrees. Positive caster means that the top of the kingpin is tilted toward the back of the vehicle. Positive caster is indicated by the sign +.

Negative caster is exactly the opposite; the top of the king pin is tilted toward the front of the vehicle. This is generally indicated by the sign -. Negative caster is sometimes referred to as reverse caster.

The effect of positive caster is to cause the vehicle to steer in the direction in which it tends to go. Positive caster in the front wheels may cause the vehicle to steer down off a crowned road or steer in the direction of a cross wind. For this reason, a number of our

modern vehicles are arranged with negative caster so that the opposite is true, which is that the vehicle tends to steer up a crowned road and into a cross wind.

Caster angle specifications are based on the vehicle load limits, which will usually result in a level frame. Since load requirements may vary, the frame does not always remain level and must be considered when determining the correct caster angle.

Because of their naturally straight running characteristics, front wheel drive vehicles are not overly sensitive to caster, therefore caster is not adjustable.

To measure the caster angle, the vehicle should be on a smooth and level surface. Place a bubble protractor on the frame rail and measure the degree of frame tilt and in what direction, either front or rear.

Two methods of determining caster angles are used. The first method is to determine the caster angle from the wheel with alignment equipment, and the second method is to obtain the desired caster angle from the specification charts. The frame angle is then added to or subtracted from the caster angles as necessary.

METHOD ONE

1. Determine the frame angle.
 - a. If the frame is high at rear, than the frame angle is negative.
 - b. If the frame is low at rear, than the frame angle is positive.
2. Determine the caster angle at the wheel with the alignment checking equipment.
3. Add or subtract frame angle to determine caster angle.
 - a. Negative frame angle is added to positive caster angle.
 - b. Positive frame angle is subtracted from positive caster angle.
 - c. Negative frame angle is subtracted from negative caster angle.
 - d. Positive frame angle is added to negative caster angle.
4. Determine the correct caster angle and the specified caster angle. Correct the vehicle caster, as required.

METHOD TWO

1. Measure the frame angle.
 - a. If the front of the frame is down than the frame angle is positive.
 - b. If the front of the frame is up than the frame angle is negative.
2. From the specifications, determine the specified or desired caster setting.
3. Add or subtract the frame angle from the specified caster setting.
 - a. Positive frame angle is subtracted from the specified setting.

- b. Negative frame angle is added to the specified caster setting.

4. Using wheel alignment equipment, obtain the measured caster angle from the wheel and determine the corrected specified setting.

KINGPIN INCLINATION ANGLE

In addition to the caster angle, the kingpins, if equipped, (or knuckle support pivots) are also inclined toward each other at the top. This angle is known as kingpin inclination and is usually spoken of, and measured, in degrees.

The effect of kingpin inclination is to cause the wheels to steer in a straight line, regardless of outside forces such as crowned roads, cross winds, etc., which may tend to make the vehicle steer at a tangent. As the spindle is moved from extreme right to extreme left it apparently rises and falls. The spindle reaches its highest position when the wheels are in the straight ahead position. In actual operation, the spindle cannot rise and fall because the wheel is in constant contact with the ground.

Therefore, the vehicle itself will rise at the extreme right turn and come to its lowest point at the straight ahead position, and again rise for an extreme left turn. The weight of the vehicle will tend to cause the wheels to come to the straight ahead position, which is the lowest position of the vehicle itself.

KINGPIN INCLUDED ANGLE

Included angle is the name given to that angle which includes kingpin inclination and camber. It is the relationship between the centerline of the wheel and the centerline of the kingpin (or the knuckle support pivots). This angle is built into the knuckle (spindle) forging and will remain constant throughout the life of the vehicle, unless the spindle itself is damaged.

When checking a vehicle on the front end alignment machine, always measure kingpin inclination as well as camber unless some provision is made on the stand for checking condition of the spindle. Where no such provision is made, add the kingpin inclination to the camber for each side of the vehicle. These totals should be exactly the same, regardless of how far from the norm the readings may be.

Since the most common cause of a bent spindle is striking the curb when parking, which causes the spindle to bend upward, the side having the greater included angle usually has the bent spindle. It will be found impossible to achieve good alignment and minimum tire wear unless the bent spindle is replaced.

TOE-IN

Toe-in is the amount that the front wheels are closer together at the front than they are at the back. This dimension is usually measured, in inches or fractions of an inch.

Generally speaking, the wheels are toed-in because they are cambered. When a vehicle operates with zero degrees camber it will be found to operate with zero toe-in. As the required camber increases, so does the toe-in. The reason for this is that the cambered wheel tends to steer in the direction in which it is cambered. Therefore it is necessary to overcome this tendency by compensating very slightly in the direction opposite to that in which it tends to roll. Caster and camber both have an effect on toe-in. Therefore toe-in is the last component on the front end which should be corrected.

TOE-OUT

When a vehicle is steered into a turn, the outside wheel of the vehicle scribes a much larger circle than the inside wheel. Therefore, the outside wheel must be steered to a somewhat less angle than the inside wheel. This difference in the angle is often called toe-out.

The change in angle from toe-in in the straight ahead position to toe-out in the turn is caused by the relative position of the steering arms to the king pin and to each other.

If a line were drawn from the center of the king pin through the center of the steering arm tie rod attaching hole at each wheel the lines would be found to cross almost exactly in the center of the rear axle.

If the front end angles, including toe-in, are set correctly, and the toe-out is found to be incorrect, one or both of the steering arms are bent.

TRACKING

While tracking is more a function of the rear axle and frame, it is difficult to align the front suspension when the vehicle does not track straight. Tracking means that the centerline of the rear axle follows exactly the path of the centerline of the front axle when the vehicle is moving in a straight line.

On vehicles that have equal tread, front and rear, the rear tires will follow in exactly the thread of the front tires, when moving in a straight line. However, there are many vehicles whose rear tread is wider than the front tread. On such vehicles, the rear axle tread will straddle the front axle tread an equal amount on both sides, when moving in a straight line.

Perhaps the easiest way to check a

vehicle for tracking is to stand directly in back of it and watch it more in a straight line down the street. If the observer will stand as near to the center of the vehicle as possible, he can readily observe, even with the difference in perspective between the front and rear wheels, whether or not they are tracking properly. If the vehicle is found to track incorrectly, the difficulty will be found in either the frame or in the rear axle alignment.

Another more accurate method to check tracking is to park the vehicle on a level floor and drop a plumb line from the extreme outer edge of the front suspension lower A-frame. Use the same drop point on each side of the vehicle. Make a chalk line where the plumb line strikes the floor. Do the same with the rear axle, selecting a point on the rear axle housing for the plumb line.

Measure diagonally from the left rear mark to the right front mark and from the right rear mark to the left front mark. These diagonal measurements should be the same but a $\frac{1}{4}$ in. variation is acceptable.

If the diagonal measurements taken are different, measure from the right rear mark to the right front mark and from the left rear to the left front. These measurements should also be the same within $\frac{1}{4}$ in.

If the diagonal measurements are different, but the longitudinal measurements are the same, the frame is swayed (diamond shaped).

However, in the event that the diagonal measurements are unequal and the longitudinal measurements are also unequal, and the vehicle is tracking incorrectly, the rear axle is misaligned.

If the diagonal and longitudinal measurements are both unequal, but the vehicle appears to track correctly on the street, a kneeback is indicated.

NOTE: A kneeback means that a complete side of the front suspension is bent back. This is often caused by crimping the front wheels against the curb when parking the vehicle, then starting up without straightening the wheels out.

Tire and Wheel Service

TIRE AND WHEEL BALANCE

There are 2 types of tire and wheel balancing procedures. They are the dynamic balance and the static balance.

The dynamic balance is the equal distribution of weight on each side of the centerline, so that when the tire and wheel assembly spins there is no tendency for the assembly to move

from side to side. Tire and wheel assemblies that are dynamically unbalanced may cause wheel shimmy.

The static balance is the equal distribution of weight around the wheel. Tire and wheel assemblies that are statically unbalanced cause a bouncing action called wheel tramp. This condition will eventually cause uneven tire wear.

Before the tire and wheel assembly can be properly balanced all deposits of mud, etc. must be removed from the inside of the rim area. Stones and other foreign matter should be removed from the tire tread area. The tire and wheel assembly should be inspected for any signs of external damage. Once these conditions have been met the tire and wheel assembly is ready to be balanced according to manufacturers instructions.

TIRE ROTATION

To ensure that all tires wear evenly tire rotation should be done every 8000 miles. If a tire shows excessive wear the wear problem should be corrected before rotating the tires. If the vehicle is equipped with a temporary spare tire, do not include it in the tire rotation procedure.

TIRE REPLACEMENT

Specialized tools and equipment have been designed for use in the replacement of a tire on multipiece rims. The manufacturers instructions should be followed in the use of the machines in the mounting and dismounting of tires to avoid personal injury.

CHRYSLER CORPORATION

Wheel Alignment

The front wheel alignment positions must be retained within the specified limits to prevent abnormal tire tread wear and to ensure steering ease.

Toe-In Adjustment

1. Secure the steering wheel with the front wheels in a straight ahead position.

2. The engine should be operating during the toe-in adjustment procedure on vehicles equipped with power steering.

3. Loosen the tie rod adjustment sleeve lock bolts or the tie rod locknuts, if equipped.

4. Rotate the tie rod adjustment sleeve or the tie rods, if equipped, to adjust the wheel toe position.

5. Tighten the adjustment sleeve lock bolts or the tie rod locknuts, if equipped.

Camber and Caster Adjustment

FRONT WHEEL DRIVE VAN/WAGON

1. Loosen the cam adjusting bolts
2. Rotate the cam bolt to move the

Tie rod adjustment—Except Front wheel drive Van/Wagon

Camber adjustment—Except Front wheel drive Van/Wagon

Toe-in adjustment—Front wheel drive Van/Wagon

Camber and caster adjustments—2WD Ram truck and Ramcharger

top of the wheel in or out to reach the specified camber, using the proper guage.

3. Tighten the cam bolts to the specified torque plus $\frac{1}{4}$ turn beyond.

4. There is no caster adjustment on these vehicles.

EXCEPT FRONT WHEEL DRIVE VAN/WAGON

1989-1990

1. Adjustments are made by loosening the retaining nuts and changing the position of the eccentric (cam) bolts, using the proper equipment.

2. Remove all the foreign material from the eccentric (cam) bolt threads.

3. Record the camber and caster measurements before making any adjustments.

4. The camber angle should be adjusted as near as possible to the preferred angle.

5. The camber angle is factory preset and cannot be adjusted on 4WD vehicles.

6. The caster can be adjusted by installing the proper size tapered shims between the front axle pads and the spring brackets.

7. The caster angle should be adjusted as near as possible to the preferred angle.

8. The caster should be the same on both sides of the vehicle.

1986-1988

1. Move both ends of the pivot bar in or out exactly equal amounts to adjust the camber.

2. The camber setting should be

Dual wheel tire rotation sequence—Ram Van/Wagon

held as close as possible to the preferred setting.

3. Rotate the pivot bar to adjust the caster. Move each end of the pivot bar exactly the same amount in opposite directions.

4. The caster should be the same on both wheels.

Steering Angle

The steering angle is measured in degrees. It has a fixed relationship with the camber angle and will not change. The angle is not adjustable.

Wheel Service

Tire Rotation

Tire rotation is recommended at 7500 miles and then at intervals of 15000 miles. More frequent rotation is permissible, if desired. When types and sizes of tires differ from front to back, tire rotation is not possible.

FORD MOTOR COMPANY

Wheel Alignment

Toe-In Adjustment

AEROSTAR

1. Start the engine and move the steering wheel back and forth several

times to place the wheel in the center position.

2. Turn the engine off and lock the steering wheel in place. Check the toe reading using the proper tools.

3. To adjust, remove the bellows seal clamp, if one was used. Free the boot from the rod and do not allow the boot to twist when the rod is turned.

4. Loosen the jam nuts and adjust the toe-in to the preferred setting with the proper tools.

5. Tighten the jam nut and replace the bellows seal clamp, if one was used.

RANGER AND BRONCO II

1. Loosen the clamp bolts at each end of the spindle connecting rod tube.

2. Rotate the sleeve until the correct toe-in reading is obtained.

3. With the clamps centered between the adjustment sleeve locking nibbs, position the bolts horizontally in the proper direction.

4. Tighten the clamp nuts and re-check the toe-in.

Camber and caster adjustment — Aerostar

Camber and caster adjustment—Ranger and Bronco II 2WD

TOP VIEW OF CAMBER/CASTER ADJUSTER

Top view of the camber/caster adjuster—Ranger and Bronco II

Camber adjustment—Ranger and Bronco II

EXCEPT AEROSTAR, RANGER AND BRONCO II

1. Loosen the clamp bolts at each end of the rod and link assembly connecting to the spindles.
2. Rotate the sleeve until the correct toe alignment is obtained.
3. Tighten the clamp nuts and recheck the toe reading.

Camber and Caster Adjustment

AEROSTAR

1. Camber and caster adjustment is provided by shims on the upper control arm.
2. Position the vehicle on suitable front end equipment and check the camber and caster reading with the proper gauges.
3. Adjust the camber and caster by loosening the 2 nuts retaining the upper control arm and adding or removing the necessary amount of shims.
4. Retighten the nuts on the upper control arm to the proper torque to prevent the loss of shims or the movement of the upper ball joint.

RANGER AND BRONCO II—2 WD

1. Camber and caster adjustment is possible using service adjusters, the adjusters are available in various degree increments. One adjuster is used to adjust both camber and caster.
2. Raise and safely support the vehicle. Remove the front wheel.
3. Remove the pinchbolt at the upper ball joint and pry the adjuster out of the axle with the proper tool.
4. Install the new service adjuster by rotating into position with the proper tool.
5. Tighten the pinchbolt, lower the vehicle and install the front wheel.

RANGER AND BRONCO II—4WD

1. The caster is not adjustable on 4WD vehicles.
2. To adjust the camber, raise and safely support the vehicle. Remove the front wheels.
3. Remove the upper ball joint cotter pin and nut.
4. Remove the camber adjuster sleeve and the adjuster from the spindle with the proper tool.
5. Install the camber adjuster on the top ball joint stud with the arrow pointing outward for positive camber and inward for negative camber. Zero camber bushings will not have an arrow and may be rotated in either direction as long as the lugs on the yoke engage the slots in the bushing.
6. Install a new nut on the lower ball joint stud and tighten.

NOTE: The camber adjuster will seat itself in the spindle at a predetermined position during the tightening sequence. Do not attempt to adjust this position.

7. Install the wheels and lower the vehicle.

E150-350

1. Camber is not adjustable on the Econoline.

2. The caster angle can be adjusted with use of a service kit or equivalent.

3. The kit includes instructions for increasing caster in $\frac{1}{2}$ degree increments by installing an adjustment cam on the bottom of the front radius arm.

BRONCO AND F150-350-2WD

1. Camber and caster adjustment is possible using service adjusters, the adjusters are available in various degree increments. One adjuster is used to adjust both camber and caster.

2. Raise and safely support the vehicle. Remove the front wheel.

3. Remove the pinchbolt at the upper ball joint and pry the adjuster out of the axle with the proper tool.

4. Install the new service adjuster by rotating into position with the proper tool.

5. Tighten the pinchbolt, lower the vehicle and install the front wheel.

BRONCO AND F150-250-4WD

1. The camber adjustment is provided by means of a series of interchangeable mounting sleeves (camber adjusters) for the upper ball joint stud.

2. To adjust, raise and safely support the vehicle. Remove the front wheels.

3. Remove the upper ball joint nut and loosen the lower ball joint nut at the end of the stud.

4. Break the spindle loose from the ball joint studs with the proper tool.

5. Remove the camber adjuster

sleeve and remove the adjuster out of the spindle with the proper tool.

6. Install the camber adjuster on the top ball joint stud with the arrow pointing outward for positive camber and inward for negative camber.

7. Install the nut on the upper ball joint and the lower ball joint stud and tighten.

8. Reinstall the wheel and lower the vehicle.

9. The caster is not adjustable on the Bronco and the F150-4WD vehicles.

10. The caster on the F250-4WD can be adjusted by inserting a shim between the spring and the axle.

11. To adjust the caster, raise and safely support the vehicle. Support the front axle independently.

NOTE: The caster should always be done on the right front axle to avoid changing the front driveshaft alignment.

12. Loosen the U-bolt nuts and separate the spring from the axle.

13. Install caster shims between the spring and the axle.

14. Position the thin edge of the shim toward the front of the vehicle to increase caster and to the rear of the vehicle to decrease caster.

15. Tighten the U-bolt nuts.

F350-4WD AND F-SUPER DUTY VEHICLES

The camber and caster is not adjustable on these vehicles.

Wheel Service

Tire Rotation

To equalize tire wear the tires and wheels should be rotated. Tire rotation is recommended at 5000-10000 mile intervals.

Tire rotation sequence—Ford trucks

GENERAL MOTORS

Wheel Alignment

Toe-In Adjustment

LUMINA APV

1. Loosen the locknut on the tie rod ends.

2. Place the steering wheel in a straight ahead position and loosen the jam nuts on the tie rod ends. Make sure that the seals (boots) do not twist.

3. Rotate the inner tie rod to obtain the proper toe angle. Check to see that the number of threads showing on each tie rod are equal.

4. Make sure that the tie rods are square then tighten the locknuts.

EXCEPT LUMINA APV

1. Determine the proper toe-in setting using suitable alignment equipment.

2. To adjust the toe-in, loosen the locknuts on the adjusting sleeve and turn the tie rod to increase or decrease the length of the tie rods.

3. When the tie rods are mounted ahead of the steering knuckle they must be decreased in length in order to increase toe-in. When the tie rod ends are mounted behind the steering knuckle they must be lengthened to increase the toe-in.

4. Tighten the locknuts on the adjusting sleeve.

Camber and Caster

LUMINA APV

1. Loosen both strut to knuckle nuts, just enough to allow movement.

2. Move the top of the wheel in or out to adjust the camber.

3. Tighten the strut to knuckle nuts.

4. The caster is not adjustable.

EXCEPT LUMINA APV AND T SERIES

1. Place the vehicle on a smooth flat surface.

2. To adjust the camber and caster, loosen the upper control arm shaft-to-frame nuts.

3. Add or subtract shims as required, tighten the nuts.

4. To adjust the camber, change shims at both the front and the rear of the shaft.

5. To adjust the caster, transfer the shims from the front to the rear or the rear to the front.

6. Tighten the nuts after selecting the proper position.

Camber and caster adjustment—Chevy truck exc. Lumina APV

10 SERIES

1. The camber and caster adjustments are made by moving the cams on the upper control arm frame mounting bolts.
2. To adjust the camber and caster, loosen the upper control arm shaft-to-frame nuts.
3. To increase positive caster, move the front cam lobe inboard and the rear cam lobe outboard.
4. To increase positive camber, move both the front and the rear cam lobes inboard.
5. Tighten the nuts after selecting the proper cam position.

Wheel Service

Tire Rotation

To equalize wear, rotate the tire and wheel assemblies every 7500 miles. Radial tires in a non-drive location may develop an irregular wear pattern that can cause increase tire noise if not rotated.

JEEP

Wheel Alignment

Toe-In Adjustment

1. Center the steering wheel and lock in position.
2. To adjust the right wheel toe, Loosen the drag link adjustment sleeve clamp bolts.

3. Turn the drag link with the proper tool until the desired setting is obtained.
4. Tighten the drag link adjustment sleeve clamp bolts.
5. To adjust the left wheel toe, loosen the clamp bolts at both ends of the tie rod.
6. Turn the tie rod with the proper tool until the desired setting is obtained.
7. Tighten the tie rod clamp bolts.

Camber and Caster

The correct wheel camber angle is pre-

set at the factory and cannot be altered by adjustment. It is important that the camber angle be the same for both wheels. If the camber angle is incorrect, the component causing the incorrect camber angle should be replaced.

1. The caster angle should be checked using suitable wheel alignment equipment.
2. Adjust the camber angle by adding or removing shims at the rear of the lower suspension arms, except on 15 and 81 model vehicles.
3. On models 15 and 81, adjust the caster angle by installing tapered

Toe-in adjustment—Jeep

Camber and caster angles—Jeep

Tire rotation sequence—Jeep

ROTATING 4 TIRES

Tire rotation sequence—Chrysler Import/Mitsubishi

shims between the front axle mounting pads and the leaf springs. On model 81, the shims must have center slots machined in them to allow clearance for the spring center bolts.

Steering Angle Adjustment

MODEL 15 VEHICLES

1. The turning angle adjustment screws are located at the rear of the steering knuckle just above the axle centerline.
2. Loosen the locknut on the turning angle adjustment screw.
3. Using a suitable turntable to measure the angle, adjust the adjustment screw to obtain the proper turning angle.
4. Turn the adjustment screw inward to increase the turning angle and outward to decrease the turning angle.
5. Tighten the adjustment screw locknut.

Wheel Service

Tire Rotation

To equalize tread wear, tires should be rotated every 7500 miles in the proper sequence.

CHRYSLER IMPORT/ MITSUBISHI

Wheel Alignment

Measure the wheel alignment with the

vehicle parked on a level ground and with the front wheels place in a straight ahead position. The front suspension, steering system tires and wheels should be serviced to the should be serviced to the proper condition prior to the measurement of the wheel alignment. Use approved wheel alignment equipment for checking the wheel alignment.

Toe-In Adjustment

1. Measure the toe-in with an appropriate toe-in guage.
2. Adjust the toe-in by turning the left and the right tie rod turnbuckles the same amount in opposite directions. The toe-in value will decrease if the left turnbuckle is turned toward the front of the vehicle and the right one is turned to the rear.
3. Adjust to specifications and tighten the tie rod turnbuckles.

Camber and Caster Adjustment RAIDER AND MONTERO

1. Adjust the tire inflation pressure to the proper specifications.
3. Remove the front wheeling hub assembly.
4. Loosen the upper arm mounting bolts and adjust by increasing or decreasing the amount of the adjusting shims between the upper arm shaft and the crossmember.
5. Remove the upper arm from the crossmember and turn the upper arm shaft to adjust the caster.

EXCEPT RAIDER AND MONTERO

1. Adjust the tire inflation pressure to the proper specifications.
2. Place the vehicle on a turning radius guage and level the vehicle.
3. Adjust the camber by rotating

the lower arm's shaft assembly on the Van/Wagon.

4. Loosen the upper mounting bolts and increase or decrease the amount of shims between the upper arm shaft and the crossmember to adjust the camber and caster except on the Van/wagon.

Wheel Service

Tire Rotation

Rotate the tires periodically to ensure uniform wear of the tires. If the spare wheel is of a different type from the other 4 wheels, the 4 wheel rotation method should be used.

ISUZU

Wheel Alignment

The wheel alignment should be checked periodically to ensure proper wear of the tires and excessive wear of the suspension components.

Toe-In Adjustment

1. Place the front wheels in straight ahead position.
2. Align a suitable toe-in guage with the center height of each wheel at the front end.
3. Apply center marks to each wheel, then take the measurement of

Measuring distance for toe-in adjustment—Isuzu

distance A between the center marks on each wheel.

4. Slowly, move the vehicle rearward until the center marks reach the rear end position.

5. Take the measurement of distance B between the center marks at the rear end.

6. The toe-in equals $B - A$.

7. To adjust the toe-in, loosen the locknut on the outer tie rod end and turn the outer track rod the same distance right and left.

Toe-in adjustment on the vehicle—
Mazda B2200 and B2600

Camber and Caster Adjustment

1. The camber angle can be adjusted by the means of camber pins installed in position between the chassis frame and the fulcrum pins. Adding shims decreases the camber angle and removing shims increases the camber angle.

2. The caster angle on the 2WD vehicles can be adjusted by varying the length of the strut bar. Adjust with the locknut. Shims should not be used for this adjustment.

3. The caster angle on the 4WD and Amigo can be adjusted by means of the caster shims installed in position between the frame and fulcrum pins. Adding shims to the front side decreases the caster angle while removing shims increases the angle. Adding shims to the rear side increases the caster angle while removing shims decreases the angle.

Tire rotation sequence—Isuzu

Checking toe-in with a suitable gauge—
Mazda

Steering Angle Adjustment

1. The maximum steering angle on the front wheels can be adjusted with the stopper bolts under the frame side members.

2. Position each front wheel on a suitable turning radius gauge in a straight ahead position.

3. Adjust the inside angle of each side with the stopper bolts.

NOTE: The maximum steering angles should be set after adjusting the front wheel alignment.

Caster angle adjustment—Isuzu 4WD
and Amigo

Wheel Service

Tire Rotation

Rotating the tires evens out tire wear and prolongs the tire life. Tire rotation should be performed every 7500 miles for maximum performance.

the marked lines at the front and the rear of the wheels.

5. To adjust, loosen the left and the right tie rod locknuts and turn the tie rods by the same degree.

6. Adjust the toe-in after adjusting the steering angle except on the MPV.

Camber and Caster Adjustment EXCEPT MPV

1. Position the front wheels on a turning radius gauge.

2. Remove the front wheel hub on 4WD vehicles.

3. Remove the wheel cap and the wheel hub nut on 2WD vehicles. Attach a suitable gauge adapter to the hub.

4. Attach a suitable camber and caster gauge to the hub or the adapter and measure the camber and the caster.

5. The camber and the caster are adjusted by adding or subtracting the amount of the shims.

MPV

1. Raise and safely support the front of the vehicle.

2. Remove the blocks that hold the mounting block to the fender.

3. Push the mounting block down and turn it to the desired position.

4. Adjust the camber and the caster by changing the position of the mounting block. Retighten the nuts to the specified torque.

MAZDA

Wheel Alignment

1. Measure the wheel alignment with the vehicle parked on a level ground and with the front wheels place in a straight ahead position.

2. The front suspension, steering system tires and wheels should be serviced to the should be serviced to the proper condition prior to the measurement of the wheel alignment. Use approved wheel alignment equipment for checking the wheel alignment.

Toe-In Adjustment

1. Raise and safely support the front of the vehicle.

2. Turn the wheels by hand, mark a line in the center of each tire tread using a proper scribing tool.

3. Place the front wheels in a straight ahead position and lower the vehicle.

4. Measure the distance between

Location of the adjusting shims for the camber and caster — Mazda

4WD

2WD

Checking the steering angle — Mazda
2WD and 4WD vehicles

4-wheel rotation

5-wheel rotation

Tire rotation sequence — Mazda

Steering Angle

The steering angle is measured by placing the front wheels on a turning radius gauge. Adjust the steering angle by adjusting the bolt fitted on the steering knuckle arm except on the MPV.

Wheel Service

Tire Rotation

In order to prolong tire life and assure

uniform wear, the tires should be rotated every 3,750 miles. Do not include the temporary spare in the rotation.

NISSAN

Wheel Alignment

Prior to any adjustments to the front wheel alignment, perform a preliminary inspection of the following:

- Check the tires for wear and proper inflation.
- Check the wheel runout.
- Check the front wheel bearings for looseness.
- Check the steering linkage and the front suspension for looseness.
- Check the operation of the front shocks.

Toe-In Adjustment

1. Draw a line across the tread of the tire and set the steering wheel in a straight ahead position.

2. Measure distance A and B at the same height as the hub center, this is the toe-in.

3. Adjust the toe-in by varying the length of the steering rods and turning the tie-rod tubes clockwise and counterclockwise an equal amount.

Toe-in adjustment - Nissan

Camber and Caster Adjustment

1. To adjust the camber and caster, increase or decrease the number of adjusting shims inserted between the upper link spindle and the frame.

NOTE: The camber, caster and the king pin inclination are preset at the factory and cannot be adjusted on the Axxess.

2. Do not install 3 or more shims at one place.

3. To adjust the camber, equalize the thickness of the front and rear shims by adding or subtracting shim(s).

4. To adjust the caster, make a difference between the front and rear shims.

5. When the caster is adjusted the camber angle changes and must be readjusted.

Steering Angle Adjustment

1. Set the wheels in a straight ahead position.

2. Move the vehicle forward until the front wheels rest on the turning radius gauge properly.

3. Rotate the steering wheel all the way to the right and the left and check the turning angle.

Wheel Service

Tire Rotation

Do not include the T type spare and small type spares in the rotation.

4 WHEELS*

5 WHEELS

DUAL WHEELS TYPE

Tire rotation sequence - Nissan

Make sure that the wheel nuts are tightened to specifications when completed.

SUZUKI/Geo

Wheel Alignment

The wheel alignment refers to the angular relationship between the front wheels, the front suspension mounting parts and the ground. Generally the only adjustment required is toe-in.

Toe-In Adjustment

The toe is adjusted by changing the tie rod length. Adjust by loosening the locknuts first the rotate the left and the right tie-rod by the same amount. In this adjustment the left and the right tie rod should become equal in length.

Toe-in adjustment - Suzuki/Geo

4 WHEEL ROTATION
[Radial Tires]

Tire rotation sequence - Suzuki/Geo

Camber and Caster Adjustment

The camber and caster cannot be adjusted for this vehicle. To prevent any possible incorrect reading of the camber or caster, move the front of the vehicle up and down a few times before inspection.

Wheel Service

Tire Rotation

To equalize tire wear, rotate the tire and wheels at 7500 miles and every 15000 miles thereafter. The tire and wheel assemblies should be rotated whenever uneven tire wear is noticed.

TOYOTA

Wheel Alignment

Follow the specific instructions of the equipment manufacturer the wheel alignment.

Toe-In Adjustment

1. Rock the vehicle up and down to stabilize the suspension.

24 ALIGNMENT

Toe-in adjustment—Toyota

Front Adjusting Cam

Rear Adjusting Cam

Camber and caster adjustment—Toyota 4WD vehicles

2. Mark the center of each rear tread at spindle height and measure the distance between the marks on the right and left tires.

3. Advance the vehicle until the marks on the rear side of the tires come to the front.

NOTE: The toe-in should be measured at the same point on the tire and at the same level.

4. Measure the distance between the marks on the front side of the tires.

5. Adjust the toe-in by turning the left and the right tie rod tubes an equal amount. Make sure that the tie rods are the same length.

Camber and Caster Adjustment

1. For 2WD trucks, adjust the camber and the caster by adding or removing shims on the upper arm. If the steering axis inclination is not as speci-

Camber and caster adjustment—Toyota 2WD vans

Steering wheel angle—Toyota

fied after the camber and caster have been properly adjusted, recheck the steering knuckle for bending or looseness.

2. For 2WD vans, adjust the camber and caster by turning the adjusting cam or the strut bar nut. The adjusting cam should not be turned more than 4.5 graduations from the neutral position. Do not turn the strut bar more than 3 threads from the original position.

3. For 4WD vehicles, adjust the camber and the caster by adjusting the front and rear adjusting cams. Refer to the service specifications for the adjustment standards.

Steering Angle Adjustment

1. Remove the caps of the steering knuckle stopper bolts.

2. Loosen the knuckle stopper bolt locknuts and tighten the stopper bolts by hand.

RADIAL TIRES

4-WHEEL

5-WHEEL

Tire rotation sequence—Toyota

3. Remove the boot clips and loosen the tie rod end locknuts.

4. Adjust the maximum wheel angle by turning the left and the right tie rod ends an equal amount.

5. Check that the lengths of the left and right tie rod are the same distance

Wheel Service

Tire Rotation

It is recommended that the tires and wheels be rotated every 7500 miles to ensure uniform wear.

VOLKSWAGEN

Wheel Alignment

The vehicle should have been run from 625-1250 miles to let the coil springs settle before performing an alignment. The vehicle should be empty.

Toe-In Adjustment

FRONT WHEELS

1. Place the steering gear in the center position by turning the steering wheel from lock to lock and count the number of turns. Turn the wheel back 1/2 the number of turns.

2. Align the lug on the rubber washer on the pinion shaft with the notch in the steering housing.

3. Loosen the locknuts and turn both tie rods until the desired setting is reached. Retighten the locknuts.

4. Check that the bellows are not twisted after turning the tie rods.

5. The specification of the total toe at the front axle is determined by the ride height of the vehicle.

Camber and Caster Adjustment

FRONT WHEELS

1. Adjust the caster by adjusting the length of the radius bar A at location B.

Front suspension components—Volkswagen Vanagon

Tire rotation sequence—Vanagon

2. To adjust the camber, loosen the nut on the upper control arm shaft. Turn the upper control arm shaft to obtain the desired setting. Tighten the nut.

Toe-In Adjustment

REAR WHEELS

1. Loosen the inner bolt on the trailing arm.
2. Adjust the toe by moving the trailing arm to the front or rear, using the proper tool.
3. Tighten the bolt.

Camber Adjustment

REAR WHEELS

1. Loosen the outer bolt on the trailing arm.
2. Adjust the camber by moving the trailing arm up or down with the proper tool.
3. Tighten the bolt.

Wheel Service

Tire Rotation

It is recommended that the tires and wheels be rotated every 7500 miles to ensure uniform wear. After the rotation torque the wheel nuts diagonally.

TIRE AND WHEEL DIAGNOSIS

Condition	Cause	Correction
Tires show excess wear on edge of tread	1) Under inflated tires 2) Vehicle overloaded 3) High-speed cornering 4) Incorrect toe setting	1) Adjust air pressure in tires 2) Correct as required 3) Correct as required 4) Set to to specification
Tires show excess wear in center of tread	1) Tires over inflated	1) Adjust air pressure in tires
Other excessive tire wear problems	1) Improper tire pressure 2) Incorrect tire/wheel usage 3) Loose or leaking shock absorbers 4) Front end out of alignment 5) Front wheel bearings out of adjustment 6) Loose, worn or damaged suspension components, bushings and ball joints 7) Wheels and tires out of balance 8) Excessive lateral and/or radial runout of wheel or tire 9) Tires need rotating	1) Adjust air pressure in tires 2) Install correct tire and wheel combination 3) Tighten or replace as necessary 4) Align front end 5) Adjust front wheel bearings 6) Inspect, repair or replace as required 7) Balance wheels and tires 8) Check, repair or replace as required. Use dial indicator to accurately determine runout 9) Rotate tires
Excessive vehicle vibration, rough steering, or severe tire wear	1) Loose or improper attaching parts 2) Overloading or unbalanced loads	1) Tighten or replace 2) Check wheel and tire specs against work load requirements. Recommend correct tire and rim. Check on loading procedure
Vehicle vibrations	1) Loose or worn driveline or suspension parts 2) Improper front end alignment 3) Excessive lateral runout (wheel or tire). Use a dial indicator to accurately verify runout reading 4) Bent or distorted wheel disc from overloading, road impact hazards or improper handling 5) Loose mountings—damaged studs, cap nuts, enlarged stud holes, worn or broken hub face or foreign material on mounting surfaces 6) Out-of-balance wheel and/or tire or hub and drum assembly 7) Out-of-round wheel or tire (excessive radial runout). Use a dial indicator to accurately verify runout reading 8) Wheel stud runout 9) Water in tires	1) Identify location of vibration carefully as it may be transmitted through frame making a rear end vibration appear to come from the front. Repair or replace loose and worn parts 2) Align front end 3) Replace wheel or tire 4) Replace wheel. Attempts to straighten wheel can result in fractures in the steel and weakening of the disc or the weld between disc and rim. Check loading and operating conditions and shop practices 5) Tighten and/or replace worn or damaged parts. Clean mounting surfaces 6) Determine the out-of-balance component and balance or replace 7) Replace the wheel or tire and check for overloading and unbalanced loads, rugged operating conditions, proper wheel and tire specifications 8) Replace hub or axle shaft 9) Remove water

TIRE AND WHEEL DIAGNOSIS

Condition	Cause	Correction
Wheel mounting is difficult	1) Improper application or mismatched parts, including studs and nuts 2) Corroded or worn parts	1) Follow manufacturers' specifications 2) Clean or replace
Wheel-rust or corrosion	1) Poor maintenance	1) Keep clean and protect with paint
Cracked or broken wheel discs. Cracks develop in the wheel disc from hand hole to hand hole, from hand hole to rim, or from hand hole to stud. Stud holes become worn, elongated or deformed. Metal builds up around stud hole edges, cracks develop from stud hole to stud hole. Related driver complaints: unusual operating noise or vibration and on the road failures	1) Metal fatigue resulting from abusive handling 2) Vehicle operated with loose wheel mounting	1) Replace wheel. Check position of wheel on vehicle for working load specifications 2) Replace wheel and check for: — Installation or correct studs and nuts, and recommend exact specifications — Cracked or broken studs, and replace — Worn hub face. Machine if not excessive, or replace if severe — Broken or cracked hub barrel, replace — Worn stud grooves, replace or install recommended serrated bolts — Clean mounting surfaces and re-torque cap nut periodically NOTE: Rust streaks fanning out from stud holes are a sure indication that the cap nuts are or have been loose
Cracks develop in rim base back flange (rim bead seat) or the gutter area (drop well radii)	1) Overloading or abuse 2) Improper use of tools	1) Replace rim or wheel. Check loading and operating conditions. Avoid over inflation of tires. Check specs for rim load capacity, working loads, tire size, ply rating and tire construction 2) Check mounting, demounting, and maintenance procedures
Damaged stud threads	1) Sliding wheel across studs during assembly	1) Replace studs. Follow proper wheel installation procedure
Loose drum	1) Stud too long	1) Replace stud with proper length stud
Broken studs	1) Loose lug nuts 2) Overloading	1) Replace studs. Follow proper torque procedure 2) Replace studs. Compare actual load against vehicle load ratings
Stripping threads	1) Excessive torque	1) Replace studs. Follow proper torque procedure
Rust streaks from stud holes	1) Loose lug nuts	1) Check complete assembly. Replace damaged parts. Follow proper torque procedure
Damaged lug nuts	1) Loose wheel assembly	1) Replace lug nuts. Check for proper stud standout. Follow proper torque procedure

TIRE AND WHEEL DIAGNOSIS

Condition	Cause	Correction
Frozen lug nuts	1) Corrosion or galling	1) If corrosion is slight, wire brush away corrosion If corrosion is excessive, replace studs and nuts If condition persists, lubricate first three threads of each stud with a graphite-based lubricant NOTE: Do not permit lubricant to get on cone seats of stud holes or on cone face of lug nuts

DOMESTIC DRIVE AXLES

Drive Axle Types

FULL FLOATING AXLES

Support of the vehicle and the payload weight is by the axle housing. The wheels are driven by splined shafts which float within the axle housing.

SEMI-FLOATING AXLE

This axle design provides for the support of the payload and vehicle weight to be carried by the axle shaft through the wheel bearings to the axle housing.

SINGLE REDUCTION AXLE

Final drive ratio is obtained by the use of a single ring gear and pinion set.

LOCK-UP TYPE DIFFERENTIALS

Unlike the standard differential, the locking differential equally divides the torque load between the driving wheels. The vehicle equipped with a locking differential can be operated on any surface (sand, snow, etc.) with a minimum of slippage through one wheel and provides the greatest power to the wheel getting traction. The vehicle with the standard differential provides power to the wheel that's easiest to turn; that is, the one experiencing the poorest traction while the other wheel may be gripping well.

When negotiating a turn, the locking differential allows the outer wheel to turn faster than the inner. When traveling in a straight direction, and the vehicle loses traction over a rough or slippery road, the clutches will lock-up and neither wheel will spin. A speci-

fied lubricant must be used for locking differentials.

The overhaul procedures are basically the same as for the conventional rear axle assemblies. The noted differences are within the differential carrier case where the lock-up mechanism is located. In some instances where wear is noted within the lock-up mechanism, the lock-up assembly should be replaced as a unit.

Drive Axle Service

COMPONENT INSPECTION AND REPLACING

Cleaning Bearings

Proper bearing cleaning is important. Bearings should always be cleaned separately from other rear axle parts.

1. Soak all bearings in clean kerosene or diesel fuel oil.

NOTE: Ordinary gasoline should not be used nor should bearings should not be cleaned in hot solution tank.

2. Slush bearings in cleaning solution until all oil lubricant is loosened. Brush bearings with soft bristled brush until all dirt has been removed. Remove loose particles of dirt by striking flat against a wood block.

3. Rinse bearings in clean fluid. While holding races to prevent rotation, blow dry with compressed air.

NOTE: Do not spin bearings while drying.

4. After bearings have been inspected, lubricate thoroughly with regular axle lubricant; then wrap each bearing in clean cloth until ready to use.

Cleaning Parts

Immerse all parts in cleaning fluid and clean thoroughly. Use a stiff bristle brush as required to remove foreign deposits. Clean all lubricant passages or channels in pinion cage, carrier, caps and retainers. Make certain the interior of housing is thoroughly cleaned. Clean vent plugs and breathers.

Small parts such as cap screws, bolts, studs, nuts and etc., should be cleaned thoroughly.

Inspection

Magna flux all steel parts, except ball and roller bearings, to detect presence of wear and cracks.

Bearings

Rotate each bearing and check to see if the rollers are worn, chipped, rough or

in any other way damaged. Check the cage to see if it is in any way damaged. If either the bearing rollers or the cage are damaged the bearing must be replaced.

Gears

Examine drive gear and drive pinion, differential pinions and differential side gears carefully, for damaged teeth, worn spots in surface hardening, distortion and where drive gear is attached to differential case with rivets, inspect rivets for looseness, replace loose rivets. Check radial clearances between differential side gears and differential case. Check fit of differential pinions on spider.

Differential Case

Inspect case for cracks, distortion or damage, if in good condition, thoroughly clean case and cover; then assemble case with bolts and mount in lathe centers of V-block stand. If lathe is not available, install differential side bearings and mount case in differential carrier. Install dial indicator and check differential case run out.

Differential case with drive gear installed is checked in the same manner, except the dial indicator reading must be taken at the gear instead of the case flange.

Axle Shafts

Examine splined end of axle shaft for twisted or cracked splines, twisted shaft and worn dowel holes in flange; install new shafts, if necessary.

Install axle shaft assembly in lathe centers and check shaft run-out with dial indicator so the indicator shaft end contacts inner surface of flange near outer edge of flange and check flange run-out.

Shims

Carefully inspect shims for uniform thickness. Where various thickness of shims are used in a pack, it is recommended the thickest shims be used between the thin shims.

Thrust Washers

Replace all thrust washers.

Spider Arms

Carefully inspect spider arms for wear or defects.

Differential Pinion Bushings

Examine bushings (when used) for excessive wear, looseness or damage. Check fit of gears on spider for excessive clearance.

Axle Housing Sleeves

Sleeves showing damaged threads, wear or other damage should be replaced, if a hydraulic press is available, otherwise replace housing.

Checking the drive gear run-out

Housing Check**BEFORE REMOVAL**

A check for bent axle housing can be made with unit in vehicle; however, conventional alignment instruments can be used, if available.

1. Raise and safely support rear axle. Block the axle under each spring seat.

2. Check wheel bearing adjustment and adjust, if necessary; then, check wheels for looseness and tighten wheel nuts, if necessary.

3. Place a chalk mark on outer side wall of tires at bottom. Measure across tires at chalk marks with a toe-in gauge.

4. Turn wheels half-way around so the chalk marks are positioned at top of wheel. Measure across tires again. If measurement at top is $\frac{1}{8}$ in. or more, smaller than measurement at bottom of wheels, axle housing has sagged and is bent. If measurement at top exceeds bottom dimension by $\frac{1}{8}$ in. or more, axle housing is bent at ends.

5. Turn chalk marks on both wheels so the marks are level with axle and at rear of vehicle. Take measurement with toe-in gauge at chalk marks; then, turn both chalk marks to front and level with axle and take another measurement. If measurement at front exceeds rear dimension by $\frac{1}{8}$ in. or more, axle is bent to the rear. If the measurement condition is the reverse, the axle is bent forward.

AFTER REMOVAL

Place two straightedges across the housing flanges and measure the distance between the ends of the straightedges at a point 11 inches from the tube center. Relocate the straightedge 180 degrees and remeasure. If the straightedges are parallel in both measurements within $\frac{3}{32}$ in., the housing is serviceable.

Oil Seal

Surface of parts, contacted by oil seals must be free of corrosion, pits and grooves. When abrasive cleaning fails to clean up the seal contact surface and restore smooth finish, a new part must be installed.

Oil seals can be removed with a drift pin. When removing a seal, be careful it does not become cocked and result in damage to the retainer. Clean surface of retainer carefully, so the seal will seat properly in retainer. Coat outer surface of seal retainer with a light coat of sealer, to prevent lubricant leaks. Carefully start seal in retainer. Cutting, scratching or curling of lip of seal seriously impairs its efficiency and usually results in premature replacement. Lip of seal should be coated with a high temperature grease con-

taining zinc oxide to help prevent scoring and damage to parts during installation. Seals must always be installed so the seal lip is toward the lubricant.

Pinion Bearing (Preload)

Pinion bearing must be adjusted for preload before assembly is installed in carrier.

1. With pinion bearings and adjusting spacers (or shims) installed in cage, check bearing contact by rotating cage.

2. Using a press, apply pressure (approx. 20,000 lbs.) to outer bearing.

3. Wrap soft wire around cage and pull on horizontal line with spring scale. Rotating (not starting) torque should be within limits recommended by manufacturer.

Method of checking the axle housing alignment with full floating axles

Checking the housing alignment with straight edge bars

Checking the pinion pre-load

NOTE: Method of determining inch-pounds torque with scale is to determine radius of cage. Multiply radius in inches by pounds pull required to rotate cage to determine inch-pounds torque. Example: An 8 in. diameter divided by 2 equals 4 in. radius. Multiply 4 in. (radius) by 5 pounds (pull) equals 20 in. pounds torque.

4. If press is not available, check preload torque by installing propeller shaft yoke, washer, and nut and torque to specifications; then check as

previously explained. Remove yoke after correct adjustment is obtained.

Bevel Gear Shaft Bearing Adjustment

Bevel gear shaft bearings must be adjusted for preload before pinion and cage assembly and differential assembly are installed in carrier.

1. Wrap several turns of soft wire around gear teeth on cross shaft and pull on a horizontal line with spring scale. Rotating (not starting) torque should be used.

Checking the pre-load on bevel gear cross shaft

NOTE: Method of determining inch lbs. torque with scale is to determine radius. Multiply radius in inches by pounds pull required to rotate shaft to determine inch-pounds torque. Example: An 8 in. diameter divided by 2 equals 4 in. radius times 5 pounds (pull) equals 20 inch lbs. torque.

2. Remove or add shims from under cage or cap opposite bevel gear to obtain specified bearing preload.

3. When making bevel gear and pinion tooth contact or backlash adjustments it is sometimes necessary to remove or add shims from one side.

NOTE: Always remove or add an equal thickness to the opposite side so to maintain correct preload.

Gear Tooth Contact and Backlash**PINION DEPTH MEASUREMENT METHOD**

Methods of adjusting pinions to obtain the proper depths will vary with the axle type and the manufacturers recommendations. Pinion depth settings and gear teeth contact may be determined by the use of pinion setting gauges or by the use of marking dye on the gear teeth.

When using the gauge method, backlash is established after the pinion has been properly set. With the dye method, backlash is obtained first, then, the proper pinion tooth contact is established.

The pinion gauge method can be a direct reading micrometer, mounted on or through an arbor bar, set in

adapter discs and located in the side carrier bearing cup locations on the differential housing and held in place by the bearing cup caps. The arbor bar coincides and represents the center line of the axle shafts. A reading is taken by the mounted micrometer, from the arbor bar to the head of the pinion to determine the need to add to or remove shims from the shim pack total, to adjust the pinion to the proper nominal assembly dimension or standard pinion depth.

Another method using the arbor bar and discs, is the use of a gauge block with a spring loaded plunger and a thumb screw to lock the plunger upon expansion. A micrometer is used to measure the gauge block after the plunger has been allowed to expand between the arbor bar and the pinion head. As in the mounted micrometer procedure, the shim pack thickness is determined by the reading obtained.

A third method is the use of a gauge block tool, installed in the housing in place of the pinion gear, and a large arbor bar placed in the axle housing differential bearing seats and tightened securely. A measurement is taken between the arbor bar and the pinion tool by either a feeler gauge or the use of individual shims from the shim pack. This measurement represents the shim pack needed for a zero marked pinion.

SETTING NEW PINION (WITHOUT GAUGE)

Whenever a pinion setting gauge is not available, the approximate thickness of the pinion shim pack at the rear pinion bearing cup, change the sign of the marking (individual variation distance) on the new pinion (plus to minus or minus to plus), then add the variation of the old pinion (sign unchanged) which will determine the amount the original shim pack must be changed when installing a new pinion.

On those types of axles where the shims are located between the pinion cage and differential carrier, change the sign of the marking (individual variation distance) on the old pinion (plus to minus or minus to plus), then, add variation of the new pinion (sign unchanged) which will determine how much the original shim pack must be altered when installing a new pinion.

When the approximate thickness of shim pack has been determined, final check of gear tooth contact must be made using dye method.

GEAR TOOTH CONTACT (DYE)

Gear tooth contact cannot be successfully accomplished until pinion and bevel gear bearings are in proper ad-

Method of measurement of the gauge block

Installment of the pinion gauge

Position of pinion setting gauge

Checking the gear backlash-bevel gear

justment and gear backlash is within specified limits.

Check for proper tooth contact by painting a few teeth of bevel gear with marking dye. Turn pinion in direction of normal rotation, then check tooth impression on bevel gear.

GEAR BACKLASH

Gears used in extended service, form running contacts due to wear of teeth; therefore, the original shim pack (be-

tween pinion cage and carrier) should be maintained when checking backlash. If backlash exceeds maximum tolerance, reduce backlash only in the amount that will avoid overlap of worn tooth section. Smoothness and roughness can be noted by rotating bevel gear.

If a slight overlap is present at worn tooth section, rotation will be rough.

If new gears are installed, check backlash with dial indicator.

Backlash is increased by moving bevel gear away from pinion and may be decreased by moving bevel gear toward pinion.

When the drive gear is attached to the differential, backlash is accomplished is differential bearing adjusting rings. It should be remembered, when one ring is tightened, the opposite ring must be loosened an equal amount to maintain previously established bearing adjustment.

On axles where the bevel gear is supported by cross shaft, backlash is accomplished by adding or removing shims under bearing cages.

Avoid overlap of worn section of gear teeth during backlash adjustments when using original gears

TERMS USED

Certain dimensions must be determined when using the pinion setting gauge:

1. **Nominal Assembly Dimension:** (standard pinion depth) This dimension (varying with axle model) is the distance between the center line of the drive gear (or differential carrier bore) and the end of the drive pinion. This dimension may be marked on the pinion or listed on the Nominal Assembly Dimension and Adapter Disc chart.

2. **Individual Variation Distance:** (pinion depth variance) This dimension is a plus or minus variation of the **Nominal Assembly Dimension** on each individual pinion which may be caused by manufacturing variations.

3. Corrected Nominal Dimension: (desired pinion depth) This dimension is the **Nominal Assembly Dimension** plus or minus the **Individual Variation Distance**.

4. Corrected Micrometer Distance is the Corrected Nominal Dimension less the thickness of the gauge set step plate (0.400 in.) mounted on end of pinion.

5. Initial Micrometer Reading is the dimension taken by micrometer to the gauge step plate.

6. Shim Pack Correction is determined by the difference between the **Corrected Micrometer Distance** and the **Initial Micrometer Reading** and represents the amount of shim pack to be added or removed as later explained.

7. Measured Pinion Depth. This measurement is the distance between the axle center line and the top of the pinion gear. If a step plate or other type gauge tool is used, this measurement is included in the total.

Pinion and Drive Gear Identification

Drive gears and pinions are tested at the time of manufacture to detect machining variances and to obtain desirable tooth contact and quietness. When the correct setting is achieved, the gears are considered matched and a set of numbers, along with other identifying marks are etched on the gear set.

A plus (+) or minus (-) sign is used, followed by a digit to represent the factory setting where the tooth contact and quietness were the best. This is called the pinion depth variance or individual variation distance.

If the pinion is marked +5 for example, this means the distance from the pinion gear rear face to the axle shaft center line is 0.005 in. more than the standard setting and if the pinion gear is marked -5, this means the distance is 0.005 in. less than the standard setting. To move the pinion to the standard setting, compensating for the variation, shims must be either added to subtracted from the total shim pack, located under the rear pinion bearing cup, between the pinion cage and the differential carrier or under the rear pinion bearing, depending upon the differential model being serviced.

The procedures to follow in the adjustment of the pinion and drive gears are outlined in the respective differential model disassembly and assembly chapters.

As a rule of thumb on the addition or removal of shims for the pinion depth adjustment, draw a diagram as shown and determine which way the

pinion must be moved to obtain the desired pinion depth.

Determining proper shim pack thickness for drive pinion depth of mesh

Nominal assembly dimension

Pinion Markings		Difference Between Markings
Old Pinion	New Pinion	
+5	+8	-3 Remove .003" Shim
+8	+5	+3 Add .003" Shim
-3	-5	+2 Add .002" Shim
-5	-3	-2 Remove .002" Shim
-3	+4	-7 Remove .007" Shim
+2	-4	+6 Add .006" Shim

The sign of the new pinion is changed and then added algebraically to the old pinion sign.

Determining pinion shim pack thickness, if the shim pack is located at the rear pinion bearing cup

Pinion Markings		Difference Between Markings
Old Pinion	New Pinion	
+8	+6	-2 Remove .002" Shims
+6	-2	-8 Remove .008" Shims
-4	+4	+8 Add .008" Shims
+2	+6	+4 Add .004" Shims
-7	-4	+3 Add .003" Shims
-2	-6	-4 Remove .004" Shims

The sign of the old pinion is changed and then added algebraically to the new pinion sign.

Determining pinion shim pack thickness, if the shim pack is located between the pinion cage and differential

Standard Torque Specifications and Capscrew Markings

Because of the varied bolt sizes used in the many models of differentials, the torque specifications are not always available for a specific bolt. By deter-

mining the grade of bolt, size and thread, the proper torque limit can be determined.

Typical gear set marking code

Movement of pinion to obtain desired pinion depth

CHRYSLER CORPORATION

Front Axle Assembly

7 1/4 INCH RING GEAR AXLE

Disassembly

DIFFERENTIAL

1. Remove the axle housing cover.
2. Clean the inside of the differential case with solvent and blow dry with compressed air.
3. Turn the differential case to make the differential pinion shaft lock screw accessible and remove the lock screw and pinion shaft.
4. Remove the left axle shaft by performing the following procedures:
 - a. Remove the C-lock from the recessed groove of the axle shaft.
 - b. Remove the axle shaft from the housing.
5. Remove the right axle shaft and inner axle shaft by performing the following procedures:

a. Remove the disconnect housing cover assembly-to-axle housing screws and the assembly and the gasket.

b. Remove the axle bearing seal retainer-to-axle housing screws and the axle/bearing retainer assembly from the axle housing.

c. Remove the shift collar from the disconnect housing.

d. Remove the C-lock from the recessed groove of the axle shaft.

e. Remove the needle bearing from the inner axle shaft.

f. Using an axle puller tool, pull the inner axle shaft from the axle housing.

6. Check for differential side-play by inserting a pry-bar between the left side of the axle housing and the differential case flange. Using a prying motion, determine whether side-play exists; there should be no side-play.

7. Paint the ring gear teeth and make a gear tooth contact pattern. Determine if proper depth of mesh can be obtained.

8. If side-play was found in step 6, proceed to step 9. If no side-play was found in step 6, check the drive gear run-out by performing the following procedures:

a. Mount a dial indicator and index the indicator stem at right angles in the rear face of the ring gear.

b. Rotate the ring gear and mark the ring gear and case at the point of greatest run-out.

c. Total indicator reading should not exceed 0.005 in.; if it does, the possibility exists that the case must be replaced.

Exploded view of the disconnect housing cover assembly—front axle assembly

Exploded view of the right axle shaft—front axle assembly

View of the inner axle shaft, bearing and shift collar—front axle assembly

Removing the needle bearing from the inner axle shaft—front axle assembly

9. Using an inch lb. torque wrench, measure and record the pinion bearing preload.

10. Matchmark the axle housing and the differential bearing caps.

11. Remove the threaded adjusters and the differential bearing caps; there is a special wrench to do this through the axle tube.

12. Remove the differential case from the housing.

NOTE: The differential bearing cups and threaded adjuster must be kept together so they can be installed in their original position.

13. Clamp the differential case and ring gear in a vise with soft jaws.

14. Remove the ring gear bolts (left-hand thread). Tap the ring gear loose with a soft-faced mallet.

15. If the ring gear run-out exceeded 0.005 in., recheck the case as follows:

a. Install the differential case, cups, caps and adjusters into the housing.

b. Turn the adjusters to eliminate all side-play and tighten the differential cap bolts snugly.

c. Measure the run-out at the ring gear flange face; total indicator reading should not exceed 0.003 in.

NOTE: It is often possible to reduce run-out by removing the ring gear and reinstalling it 180 degrees from its original position.

d. Remove the differential case from the housing.

16. Remove the pinion shaft lock-screw and remove the pinion shaft.

17. Rotate the differential side gears until the differential pinion shafts can be removed through the opening in the case.

18. Remove the differential side gears and thrust washers.

19. Using a bearing puller, press side bearing from the differential.

PINION GEAR

1. Remove the pinion nut, washer and pinion flange.

2. Remove and discard the pinion oil seal.

3. Using a brass hammer, drive the pinion rearward out of the bearing. This will result in damage to the bearing and cup. The bearing cone and cup must be replaced with new parts. Discard the collapsible spacer.

4. Using a brass drift and a hammer, drive the front and rear bearing cups from the housing.

5. Remove the shim from behind the rear bearing cup and record the thickness.

6. Using a bearing puller, press the rear bearing cone from the pinion stem.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

1. The proper pinion setting (relative to the ring gear) is determined by a shim which has been selected before the pinion is to be installed in the carrier. Pinion bearing shims are available in 0.001 in. increments.

2. The head of the pinion is marked with a plus (+) or a minus (-) mark that is followed by a number ranging from 0-4. If the old and new pinions have the same marking and the old bearing is being installed, use a shim of the original thickness. If the old pinion is marked zero (0), however and the new pinion is marked +2, try a

shim that is 0.002 in. thinner. If the new pinion is marked axle housing cup bore and install -2, try a shim that is 0.002 in. thicker.

3. Position the selected shim in the bore of the rear bearing cup. Install the cup.

NOTE: Special pinion depth measuring tools are available. When using the special tools, follow the manufacturer's recommended procedures. Without the special tools, complete the following procedure and check the pinion depth by examining the pinion to ring gear tooth contact pattern. Correct as required by adding or subtracting shims controlling the pinion depth.

4. Place the rear pinion bearing cone on the pinion stem (small side away from pinion head).

5. Lubricate the front and rear bearing cones and install the rear pinion bearing cone onto the pinion stem with an arbor press.

6. Insert the pinion bearing and collapsible spacer assembly through the carrier and install the front bearing cone. Install the companion flange.

NOTE: During installation of the pinion bearing do not collapse the spacer.

7. Install the drive pinion oil seal into the carrier; be sure to properly seat the seal.

8. Support the pinion in the carrier.

9. Install the Belleville washer (convex side up) and pinion nut.

10. Hold the companion flange and tighten the pinion nut to remove all endplay, while rotating the pinion to ensure proper bearing seating. Remove the tools and rotate the pinion several revolutions.

11. Torque the pinion nut to 210 ft. lbs. (285 Nm). Using an inch lbs. torque wrench, measure the pinion bearing preload; the torque is 20-35 inch lbs. for new bearings or 10 inch lbs. over the original figure for the old pinion bearing.

NOTE: The correct preload reading can only be obtained with the carrier nose upright. The final assembly is incorrect if the final pinion nut torque is below 210 ft. lbs. (285 Nm) or if the pinion bearing preload is not within specifications. Under no circumstances should the pinion nut be backed off to reduce the pinion bearing preload; if this is done, a new collapsible spacer will have to be installed and the unit adjusted again until proper preload is obtained.

DIFFERENTIAL

1. Lubricate all parts, before assembly, with rear axle lubricant.

2. Install the thrust washers on the differential side gears and install the side gears into the case.

3. Place thrust washers on both differential pinions and, working through the opening in the case, mesh the pinion gears with the side gears. The pinions should be exactly 180 degrees apart.

4. Rotate the side gears 90 degrees to align the pinions and thrust washers with the pinion shaft holes.

5. From the pinion shaft lockpin hole side of the case, insert the slotted end of the pinion shaft through the case and conical thrust washer; install the pinion shaft through one of the pinion gears.

6. Install a thrust block through the side gear hub, so the slot is centered between the side gears.

7. Hold all of the parts in alignment and align the lockpin holes in the pinion shaft and case. Install the lockpin from the pinion shaft side of the ring gear flange, temporarily.

8. With a stone, relieve the edge of the chamfer on the inside diameter of the ring gear.

9. Heat the ring gear (fluid bath or heat lamp) to a temperature not exceeding 300°F; do not heat ring gear with a torch.

10. Align the ring gear with the case. Insert the ring gear screws through the case flange and into the ring gear.

11. Alternately, tighten each cap screw to 80 ft. lbs. (108 Nm).

12. Position each differential bearing cone on the hub of the differential case (taper away from ring gear) and install the bearing cones; a shop press may be helpful.

13. Install the differential into the axle housing.

14. Install the right and inner axle shaft by performing the following procedures:

a. Using the axle shaft removal/installation tool, install the inner axle shaft into the housing.

b. Install the C-clip on the other end of the shaft to retain it.

c. Install the needle bearing into the end of the inner axle shaft.

d. Install the shift collar onto the splined end of the inner axle shaft.

e. Install the axle shaft/bearing retainer assembly into the disconnect housing and torque the bearing retainer-to-disconnect housing screws to 200 inch lbs. (23 Nm).

f. Using a new gasket, install the disconnect housing cover assembly onto the disconnect housing and torque the bolts to 10 ft. lbs. (14 Nm).

15. Install the left axle shaft into the axle housing and secure it with the C-clip.

16. To complete the installation, reverse the removal procedures.

Adjustment

DIFFERENTIAL BEARING PRELOAD AND RING GEAR-TO-PINION BACKLASH

The threaded adjuster uses a hex drive hole and requires a special tool C-4164 to adjust the side bearing preload through the axle tube. An adjuster lock with 2 pointed teeth which engage in the exposed adjuster thread when the lock is tightened is provided. The shims will range from 0.020-0.038 in. and will be equipped with internal centering tabs. The shims, marked with a number which represents its thickness in thousandths of an in., can be installed with either side against the pinion head.

1. Index the gears so the same gear teeth are in contact throughout the adjustment.

2. The differential bearing cups will not always move with the adjusters. It is important to seat the bearings by rotating them 5-10 times in each direction, each time the adjusters are moved.

3. With the pinion bearings installed and the preload set, install the differential with adjusters, caps and bearings. Lubricate the bearings and adjuster threads. Tighten the top cap screws on the right and left to 10 ft. lbs. Tighten the bottom cap screws finger tight until the head is just seated on the bearing cap.

4. Using the tool, make sure the adjuster rotates freely. Turn both adjusters in until bearing play is eliminated with some drive gear backlash (0.010 in.). Seat the bearing rollers.

5. Install and register a dial indicator against the drive side of a gear tooth. Check the backlash at 4 positions to find the point of minimum backlash. Rotate the gear to the position of least backlash and mark the tooth so the readings will be taken at the same point.

6. Loosen the right adjuster and turn it until the backlash is 0.003-0.004 in. with each adjuster tightened to 10 ft. lbs. Seat the bearing rollers.

7. Tighten the differential bearing cap screws to 45 ft. lbs. (61 Nm).

8. Tighten the right adjuster to 70 ft. lbs. and seat the rollers, until the torque remains constant at 70 ft. lbs. Measure the backlash, if the backlash is not 0.006-0.008 in. increase the torque on the right adjusters and seat the rollers until the correct backlash is obtained.

Sectional view of the of the left disconnect axle assembly—model 44 front axle assembly

9. Tighten the left adjuster to 70 ft. lbs. and seat the bearings until the torque remains constant.

10. If the assembly is properly done, the initial reading on the left adjuster will be approximately 70 ft. lbs. If it is substantially less, the entire procedure should be repeated.

11. After the adjustments are complete, install the adjuster locks; be sure the teeth are engaged in the adjuster threads. Torque the lockscrews to 90 inch lbs.

SPICER MODEL 44 AXLE

Disassembly

DIFFERENTIAL

1. Remove the housing cover and drain the lubricant.

2. Remove the left axle shaft and the inner axle shaft by performing the following procedures:

a. Using an axle puller, press the left axle shaft from the axle housing.

b. Remove the disconnect housing assembly-to-axle housing screws, the housing and the gasket.

c. Remove the shift collar from the inner axle shaft.

d. Using an inner axle shaft removal/installation tool, attach it to the inner axle shaft and carefully, slide the inner axle shaft from the axle housing.

3. Using an axle spreader tool, mount it onto the axle housing and spread the housing enough to remove the differential.

4. Using a dial indicator, measure the amount the opening is being spread; do not spread the housing more than 0.015 in. (0.38mm), for damage to the housing may occur.

5. Mark the differential bearing caps for reassembly purposes.

6. Loosen the bearing caps until 2–3 threads are engaged.

7. Using a prybar, pry the differential loose.

8. Remove the bearing caps and the differential.

9. Mount the differential into a vise.

10. Remove and discard the ring gear bolts; they are not reusable.

11. Using a brass drift and a hammer, tap the ring gear from the differential.

Removing the inner axle shaft—model 44 front axle assembly

12. Using a differential bearing puller, press the differential bearings from the differential.

13. Remove the differential bearing shims.

14. Remove the pinion shaft lockpin and pinion shaft.

15. Rotate the pinions to remove them through the case opening.

16. Remove the side gears and thrust washers.

PINION GEAR

1. Remove the differential case from the axle housing.

2. Using a pinion yoke holding tool, remove the pinion gear nut.

3. Remove the pinion washer. Using a pinion yoke holder tool and a pinion puller tool, press the yoke from the pinion gear.

4. Using an oil seal remover tool, remove the pinion gear oil seal and discard it. Remove the slinger, the gasket, the upper pinion bearing cone and preload shim pack; measure and record the shim thicknesses.

5. Press drive the pinion gear and inner bearing cone assembly from the axle housing.

6. Using a shop press, press the inner bearing cone from the pinion gear.

7. Remove and record the shim thicknesses from behind the inner pinion bearing cup.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

1. Make sure the ring and pinion are a matched set.

2. Measure the thickness of the

original pinion shim and note the variance on the pinion gear.

3. Perform the following procedure to determine the pinion starter shim thickness:

a. If the original ring and pinion are being installed, use the original shim.

b. If a replacement gear set is being installed, determine the best starter shim thickness.

c. Refer to the pinion variance chart and observe where the old and new pinion marking column intersect.

d. If the old pinion is +2 and the new pinion is -2, the intersecting figure is +0.004 in. (0.10mm); add this amount to the original shim. Or, if the old pinion is -3 and the new pinion is -2, the intersecting figure is -0.001 in. (-0.025mm); subtract this amount from the original shim.

4. Install the starter shim in the pinion rear bearing cup bore; if the shim is chamfer on one side, position the chamfered side so it faces the bottom of the bore.

5. Using a driver tool, install the pinion rear bearing cup into the axle housing.

6. Install the front bearing cup.

7. Using a shop press, press the rear bearing onto the pinion gear.

8. Install the pinion gear into the axle housing and the front bearing onto the pinion; do not install the slinger or the seal.

9. Install the yoke, the pinion nut washer and the old pinion nut; tighten the nut enough to remove the endplay.

10. Adjust the backlash and gear tooth contact.

DIFFERENTIAL

1. Install the side gears, the thrust washers and the pinion gears into the differential case.

NOTE: If new gears and washers are used, it will not be necessary to check the gear backlash. Correct fit is provided due to the close manufacturing tolerances.

2. Install the pinion shaft and lockpin into the case.

3. Assemble the original differential bearing shim packs, then, remove approximately 0.20 in. (0.50mm) shim thickness from each pack; the remaining shims will serve as a starter shim pack.

4. Install the starter shim packs and bearing onto the case.

5. Align and install the ring gear. Using new bolts, torque the ring gear-to-differential case bolts to 45-60 ft. lbs. (61-81 Nm).

6. Install the spreader tool onto the axle housing. Using a dial indicator, spread the axle housing no more than 0.015 in. (0.38mm).

NOTE: Do not spread the housing more than 0.015 in. (0.038mm), for damage may occur to the case.

7. Install the differential; it may be necessary to tap the differential bearing cups, with a soft hammer, to seat them.

8. Install the differential bearing caps and torque the bolts to 70-90 ft. lbs. (95-122 Nm).

9. Remove the spreader tool and dial indicator.

10. Adjust the ring and pinion gear.

Installing the inner axle shaft bearing—model 44 front axle assembly

11. Using silicone sealant, apply a bead of it to the axle housing. Install the cover and torque the bolts to 35 ft. lbs. (47 Nm).

Adjustment

PINION BEARING PRELOAD

1. Using a yoke holding tool, torque the pinion nut to 200-220 ft. lbs. (271-298 Nm). Rotate the drive pinion several complete revolutions to seat the bearing rollers.

2. Using an inch lb. torque wrench, measure the torque necessary to rotate the pinion; the torque should be 20-40 inch lbs. (2-5 Nm).

NOTE: If the torque is not correct, add a shim to decrease the preload or subtract a shim to increase the preload.

3. Remove the pinion nut, the washer and the yoke after setting the preload; be sure to discard the old nut.

4. Lubricate the new pinion oil seal lip and install the seal into the axle housing.

5. Install the yoke, the washer and a new pinion nut; torque the nut to 200-220 ft. lbs. (271-298 Nm).

Original Pinion Gear Depth Variance	Replacement Pinion Gear Depth Variance								
	-4	-3	-2	-1	0	+1	+2	+3	+4
+4	+0.008	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0
+3	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	-0.001
+2	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	-0.001	-0.002

25 DRIVE AXLES DOMESTIC

DIFFERENTIAL BEARING PRELOAD AND DRIVE GEAR AND PINION BACKLASH

1. Install the differential and tighten the bearing caps.

2. Using a dial indicator, mount it onto the housing, position the stylus against the drive side of one ring gear tooth; be sure the stylus is at a right angle to the tooth.

3. Move the ring gear toward the dial indicator and zero it.

4. Move the ring gear away from the pinion until the backlash and note the reading on the dial indicator.

NOTE: The reading represents the thickness of the shim pack necessary to take up the clearance between the bearing cup and the case on the ring gear side of the differential assembly.

5. Subtract this reading from the previously recorded total reading to obtain the amount of shims necessary to take up the clearance between the bearing cup and the case at the pinion side of the differential.

6. Remove the differential and ring gear assembly from the carrier.

7. Remove the differential bearing covers. Install the correct thickness shim pack between the bearing cone and differential case hub shoulder. Add an additional 0.015 in. (0.38mm) shim to the drive gear side of the differential and install the differential bearing cones.

8. Install the spreader tool to the axle housing. Using a dial indicator, spread the housing to 0.015–0.020 (0.38–0.51mm). Install the differential assembly into the axle housing.

9. Install the bearing caps, remove the spreader tool and torque the bearing caps snugly.

10. Using a soft hammer, tap the drive gear to seat the differential bearing and cups.

NOTE: When seating the bearing and cups, be careful not to nick the ring gear or drive pinion teeth.

11. Torque the bearing cap bolts to 70–90 ft. lbs. (95–122 Nm).

12. Attach a dial indicator to the carrier, with the stylus contacting a ring gear tooth, and measure the backlash between the ring gear and the drive pinion.

13. Check the backlash at 4 equally spaced points around the circumference of the ring gear; the backlash

Exploded view of the 7 1/4 inch rear axle assembly

Exploded view of the 8 1/4 inch rear axle assembly

must be between 0.04–0.009 in. (0.102–0.229mm) and cannot vary more than 0.002 in. (0.508mm) between the 4 check positions.

NOTE: If the backlash does not fall within these specifications, change the shim pack thickness on both the differential bearing hubs to maintain the proper bearing preload and backlash.

SPICER—MODEL 60 AXLE

For overhaul information, refer to the Spicer 60 axle, in the rear axle assembly section.

Rear Axle Assembly

While some Dodge/Plymouth trucks use a 7 1/4, 8 1/4, 8 3/8 or 9 1/4 in. semi-floating axle others use a Spicer 60, 60 HD (heavy duty) or 70 full-floating axle.

7 1/4, 8 1/4, 8 3/8 AND 9 1/4 INCH RING GEAR AXLE

Disassembly DIFFERENTIAL

1. Remove the axle housing cover.
2. Clean the inside of the differential case with solvent and blow dry with compressed air.
3. Check for differential side-play by inserting a pry-bar between the left

side of the axle housing and the differential case flange. Using a prying motion, determine whether side-play exists; there should be no side-play.

4. Paint the ring gear teeth and make a gear tooth contact pattern. Determine if proper depth of mesh can be obtained.

5. If side-play was found in step 3, proceed to step 6. If no side-play was found in step 3, check the drive gear run-out by performing the following procedures:

- a. Mount a dial indicator and index the indicator stem at right angles in the rear face of the ring gear.
- b. Rotate the ring gear and mark the ring gear and case at the point of greatest run-out.

25 DRIVE AXLES DOMESTIC

- c. Total indicator reading should not exceed 0.005 in.; if it does, the possibility exists that the case must be replaced.
6. Using an inch lb. torque wrench, measure and record the pinion bearing preload.
7. Matchmark the axle housing and the differential bearing caps.
8. Remove the threaded adjusters and the differential bearing caps; there is a special wrench to do this through the axle tube.
9. Remove the differential case from the housing.

NOTE: The differential bearing cups and threaded adjuster must be kept together so they can be installed in their original position.

10. Clamp the differential case and ring gear in a vise with soft jaws.
11. Remove the ring gear bolts (left-hand thread). Tap the ring gear loose with a soft-faced mallet.
12. If the ring gear run-out exceeded 0.005 in., recheck the case as follows:
 - a. Install the differential case, cups, caps and adjusters into the housing.
 - b. Turn the adjusters to eliminate all side-play and tighten the differential cap bolts snugly.
 - c. Measure the run-out at the ring gear flange face; total indicator reading should not exceed 0.003 in.

NOTE: It is often possible to reduce run-out by removing the ring gear and reinstalling it 180 degrees from its original position.

- d. Remove the differential case from the housing.
13. Remove the pinion shaft lock-screw and remove the pinion shaft.
14. Rotate the differential side gears until the differential pinion shafts can be removed through the opening in the case.
15. Remove the differential side gears and thrust washers.
16. Using a bearing puller, press side bearing from the differential.

PINION GEAR

1. Remove the pinion nut, washer and pinion flange.
2. Remove and discard the pinion oil seal.
3. Using a brass hammer, drive the pinion rearward out of the bearing. This will result in damage to the bear-

Exploded view of the 8 3/4 inch rear axle assembly

ing and cup. The bearing cone and cup must be replaced with new parts. Discard the collapsible spacer.

4. Using a brass drift and a hammer, drive the front and rear bearing cups from the housing.

5. Remove the shim from behind the rear bearing cup and record the thickness.

6. Using a bearing puller, press the rear bearing cone from the pinion stem.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

1. The proper pinion setting (relative to the ring gear) is determined by a shim which has been selected before the pinion is to be installed in the car-

rier. Pinion bearing shims are available in 0.001 in. increments.

2. The head of the pinion is marked with a plus (+) or a minus (-) mark that is followed by a number ranging from 0-4. If the old and new pinions have the same marking and the old bearing is being installed, use a shim of the original thickness. If the old pinion is marked zero (0), however and the new pinion is marked +2, try a shim that is 0.002 in. thinner. If the new pinion is marked axle housing cup bore and install -2, try a shim that is 0.002 in. thicker.

3. Position the selected shim in the bore of the rear bearing cup. Install the cup.

NOTE: Special pinion depth measuring tools are available. When using the special tools, follow the manufacturer's recommended procedures. Without the special tools, complete the following procedure and check the pinion depth by examining the pinion to ring gear tooth contact pattern. Correct as required by adding or subtracting shims controlling the pinion depth.

4. Place the rear pinion bearing cone on the pinion stem (small side away from pinion head).

5. Lubricate the front and rear bearing cones and install the rear pinion bearing cone onto the pinion stem with an arbor press.

6. Insert the pinion bearing and collapsible spacer assembly through the carrier and install the front bearing cone. Install the companion flange.

NOTE: During installation of the pinion bearing do not collapse the spacer.

7. Install the drive pinion oil seal into the carrier; be sure to properly seat the seal.

8. Support the pinion in the carrier.

9. Install the Belleville washer (convex side up) and pinion nut.

10. Hold the companion flange and tighten the pinion nut to remove all endplay, while rotating the pinion to ensure proper bearing seating. Remove the tools and rotate the pinion several revolutions.

11. Torque the pinion nut to 210 ft. lbs. (285 Nm). Using an inch lbs. torque wrench, measure the pinion bearing preload; the torque is 20–35 inch lbs. for new bearings or 10 inch lbs. over the original figure for the old pinion bearing.

NOTE: The correct preload reading can only be obtained with the carrier nose upright. The final assembly is incorrect if the final pinion nut torque is below 210 ft. lbs. (285 Nm) or if the pinion bearing preload is not within specifications. Under no circumstances should the pinion nut be backed off to reduce the pinion bearing preload; if this is done, a new collapsible spacer will have to be installed and the unit adjusted again until proper preload is obtained.

DIFFERENTIAL

1. Lubricate all parts, before assembly, with rear axle lubricant.

2. Install the thrust washers on the differential side gears and install the side gears into the case.

3. Place thrust washers on both differential pinions and, working through the opening in the case, mesh the pinion gears with the side gears. The pinions should be exactly 180 degrees apart.

4. Rotate the side gears 90 degrees to align the pinions and thrust washers with the pinion shaft holes.

5. From the pinion shaft lockpin hole side of the case, insert the slotted end of the pinion shaft through the case and conical thrust washer; install the pinion shaft through one of the pinion gears.

6. Install a thrust block through the side gear hub, so the slot is centered between the side gears.

7. Hold all of the parts in alignment and align the lockpin holes in the pinion shaft and case. Install the lockpin from the pinion shaft side of the ring gear flange, temporarily.

8. With a stone, relieve the edge of the chamfer on the inside diameter of the ring gear.

9. Heat the ring gear (fluid bath or heat lamp) to a temperature not exceeding 300°F; do not heat ring gear with a torch.

10. Align the ring gear with the case. Insert the ring gear screws through the case flange and into the ring gear.

11. Alternately tighten each cap screw to:

80 ft. lbs. (108 Nm)–7¼ in axle

70 ft. lbs. (95 Nm)–8¼ in., 8⅜ in. and 9¼ in. axles

12. Position each differential bearing cone on the hub of the differential case (taper away from ring gear) and install the bearing cones; a shop press may be helpful.

Adjustment

DIFFERENTIAL BEARING PRELOAD AND RING GEAR-TO-PINION BACKLASH

The threaded adjuster uses a hex drive hole and requires a special tool C-4164 to adjust the side bearing preload through the axle tube. An adjuster lock with 2 pointed teeth which engage in the exposed adjuster thread when the lock is tightened is provided. The shims will range from 0.020–0.038 in. and will be equipped with internal centering tabs. The shims, marked with a number which represents its thickness in thousandths of an in., can be installed with either side against the pinion head.

1. Index the gears so the same gear teeth are in contact throughout the adjustment.

2. The differential bearing cups will not always move with the adjusters. It is important to seat the bearings by ro-

tating them 5–10 times in each direction, each time the adjusters are moved.

3. With the pinion bearings installed and the preload set, install the differential with adjusters, caps and bearings. Lubricate the bearings and adjuster threads. Tighten the top cap screws on the right and left to 10 ft. lbs. Tighten the bottom cap screws finger tight until the head is just seated on the bearing cap.

4. Using the tool, make sure the adjuster rotates freely. Turn both adjusters in until bearing play is eliminated with some drive gear backlash (0.010 in.). Seat the bearing rollers.

5. Install and register a dial indicator against the drive side of a gear tooth. Check the backlash at 4 positions to find the point of minimum backlash. Rotate the gear to the position of least backlash and mark the tooth so the readings will be taken at the same point.

Using a long bar tool with hex end to adjust the differential bearing preload and gear backlash

6. Loosen the right adjuster and turn it until the backlash is 0.003–0.004 in. with each adjuster tightened to 10 ft. lbs. Seat the bearings rollers.

7. Tighten the differential bearing cap screws to:

100 ft. lbs. (136 Nm)–8¼ in. and 9¼ in axles

45 ft. lbs. (61 Nm)–7¼ in. axle

70 ft. lbs. (95 Nm)–8⅜ in axle

8. Tighten the right adjuster to 70 ft. lbs. and seat the rollers, until the torque remains constant at 70 ft. lbs. Measure the backlash, if the backlash is not 0.006–0.008 in. increase the torque on the right adjusters and seat the rollers until the correct backlash is obtained.

9. Tighten the left adjuster to 70 ft. lbs. and seat the bearings until the torque remains constant.

10. If the assembly is properly done, the initial reading on the left adjuster will be approximately 70 ft. lbs. If it is substantially less, the entire procedure should be repeated.

11. After the adjustments are complete, install the adjuster locks; be

sure the teeth are engaged in the adjuster threads. Torque the lockscrews to 90 inch lbs.

SPICER—MODELS 60, 60 HD AND 70 RING GEAR AXLES

Disassembly

DIFFERENTIAL

1. Remove the housing cover and drain the lubricant.
2. Using an axle spreader tool, mount it onto the axle housing and spread the housing enough to remove the differential.
3. Using a dial indicator, measure the amount the opening is being spread; do not spread the housing more than 0.015 in. (0.38mm), for damage to the housing may occur.
4. Mark the differential bearing caps for reassembly purposes.
5. Loosen the bearing caps until 2-3 threads are engaged.
6. Using a prybar, pry the differential loose.
7. Remove the bearing caps and the differential.
8. Mount the differential into a vise.

9. Remove and discard the ring gear bolts; they are not reusable.

10. Using a brass drift and a hammer, tap the ring gear from the differential.

11. Using a differential bearing puller, press the differential bearings from the differential.

12. Remove the differential bearing shims.

13. Remove the pinion shaft lockpin and pinion shaft.

14. Rotate the pinions to remove them through the case opening.

15. Remove the side gears and thrust washers.

PINION GEAR

1. Remove the differential case from the axle housing.

2. Using a pinion yoke holding tool, remove the pinion gear nut.

3. Remove the pinion washer. Using a pinion yoke holder tool and a pinion puller tool, press the yoke from the pinion gear.

4. Using an oil seal remover tool, remove the pinion gear oil seal and discard it. Remove the slinger, the gasket, the upper pinion bearing cone and pre-

load shim pack; measure and record the shim thicknesses.

5. Press drive the pinion gear and inner bearing cone assembly from the axle housing.

6. Using a shop press, press the inner bearing cone from the pinion gear.

7. Remove and record the shim thicknesses from behind the inner pinion bearing cup.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Exploded view of the Spicer model 70 differential

Assembly

PINION GEAR

1. Make sure the ring and pinion are a matched set.
2. Measure the thickness of the original pinion shim and note the variance on the pinion gear.
3. Perform the following procedure to determine the pinion starter shim thickness:
 - a. If the original ring and pinion are being installed, use the original shim.
 - b. If a replacement gear set is being installed, determine the best starter shim thickness.
 - c. Refer to the pinion variance chart and observe where the old and new pinion marking column intersect.
 - d. If the old pinion is +2 and the new pinion is -2, the intersecting figure is +0.004 in. (0.10mm); add this amount to the original shim. Or, if the old pinion is -3 and the new pinion is -2, the intersecting figure is -0.001 in. (-0.025mm); subtract this amount from the original shim.
4. Install the starter shim in the pinion rear bearing cup bore; if the shim is chamfer on one side, position the chamfered side so it faces the bottom of the bore.
5. Using a driver tool, install the pinion rear bearing cup into the axle housing.
6. Install the front bearing cup.
7. Using a shop press, press the rear bearing onto the pinion gear.
8. Install the pinion gear into the axle housing and the front bearing onto the pinion; do not install the slinger or the seal.
9. Install the yoke, the pinion nut washer and the old pinion nut; tighten the nut enough to remove the endplay.
10. Adjust the backlash and gear tooth contact.

DIFFERENTIAL

1. Install the side gears, the thrust washers and the pinion gears into the differential case.

NOTE: If new gears and washers are used, it will not be necessary to check the gear backlash. Correct fit is provided due to the close manufacturing tolerances.

2. Install the pinion shaft and lockpin into the case.
3. Assemble the original differential bearing shim packs, then, remove approximately 0.20 in. (0.50mm) shim thickness from each pack; the remaining shims will serve as a starter shim pack.
4. Install the starter shim packs and bearing onto the case.
5. Align and install the ring gear. Using new bolts, torque the ring gear-to-differential case bolts to 100-120 ft. lbs. (136-163 Nm).
6. Install the spreader tool onto the axle housing. Using a dial indicator, spread the axle housing no more than 0.015 in. (0.38mm).

NOTE: Do not spread the housing more than 0.015 in. (0.038mm), for damage may occur to the case.

7. Install the differential; it may be necessary to tap the differential bearing cups, with a soft hammer, to seat them.
8. Install the differential bearing caps and torque the bolts to 70-90 ft. lbs. (95-122 Nm).
9. Remove the spreader tool and dial indicator.
10. Adjust the ring and pinion gear.
11. Using silicone sealant, apply a bead of it to the axle housing. Install the cover and torque the bolts to 35 ft. lbs. (47 Nm).

Adjustment

PINION BEARING PRELOAD

1. Using a yoke holding tool, torque the pinion nut to 250-270 ft. lbs. (339-366 Nm). Rotate the drive pinion several complete revolutions to seat the bearing rollers.
2. Using an inch lb. torque wrench, measure the torque necessary to ro-

tate the pinion; the torque should be 10-20 inch lbs. (1-3 Nm).

NOTE: If the torque is not correct, add a shim to decrease the preload or subtract a shim to increase the preload.

3. Remove the pinion nut, the washer and the yoke after setting the preload; be sure to discard the old nut.
4. Lubricate the new pinion oil seal lip and install the seal into the axle housing.
5. Install the yoke, the washer and a new pinion nut; torque the nut to 250-270 ft. lbs. (339-366 Nm).

DIFFERENTIAL BEARING PRELOAD AND DRIVE GEAR AND PINION BACKLASH

1. Install the differential and tighten the bearing caps.
2. Using a dial indicator, mount it onto the housing, position the stylus against the drive side of one ring gear tooth; be sure the stylus is at a right angle to the tooth.
3. Move the ring gear toward the dial indicator and zero it.
4. Move the ring gear away from the pinion until the backlash and note the reading on the dial indicator.

NOTE: The reading represents the thickness of the shim pack necessary to take up the clearance between the bearing cup and the case on the ring gear side of the differential assembly.

5. Subtract this reading from the previously recorded total reading to obtain the amount of shims necessary to take up the clearance between the bearing cup and the case at the pinion side of the differential.
6. Remove the differential and ring gear assembly from the carrier.
7. Remove the differential bearing covers. Install the correct thickness shim pack between the bearing cone and differential case hub shoulder. Add an additional 0.015 in. (0.38mm) shim to the drive gear side of the dif-

25 DRIVE AXLES DOMESTIC

ferential and install the differential bearing cones.

8. Install the spreader tool to the axle housing. Using a dial indicator, spread the housing to 0.015–0.020 (0.38–0.51mm). Install the differential assembly into the axle housing.

9. Install the bearing caps, remove the spreader tool and torque the bearing caps snugly.

10. Using a soft hammer, tap the drive gear to seat the differential bearing and cups.

NOTE: When seating the bearing and cups, be careful not to nick the ring gear or drive pinion teeth.

11. Torque the bearing cap bolts to 70–90 ft. lbs. (95–122 Nm).

12. Attach a dial indicator to the carrier, with the stylus contacting a ring gear tooth, and measure the backlash between the ring gear and the drive pinion.

13. Check the backlash at 4 equally spaced points around the circumference of the ring gear; the backlash must be between 0.04–0.009 in. (0.102–0.229mm) and cannot vary more than 0.002 in. (0.508mm) between the 4 check positions.

NOTE: If the backlash does not fall within these specifications, change the shim pack thickness on both the differential bearing hubs to maintain the proper bearing preload and backlash.

TRAC-LOK DIFFERENTIAL

Operational Test

If a noisy or rough operation such as a chatter occurs when turning corners, the most probable cause of this chatter or noise is incorrect or contaminated lubricant. Before removing the Trac-Lok unit for repair, drain, flush and refill the axle with the specified lubricant. A complete lubricant drain and

refill with the specified fluid will usually correct the chatter problem. A quick operational test of the Trac-Lok differential can be done easily by performing the following steps.

1. Position one wheel on solid dry pavement and the opposite wheel on ice, mud grease or a similar low traction surface.

2. Gradually, increase the engine rpm to obtain the maximum traction prior to a breakaway. The ability to move the vehicle effectively will demonstrate the proper performance.

NOTE: If the test is performed on extremely slick surfaces such as ice or grease coated surfaces, some question may exist as to proper performance. In these extreme cases, a properly performing Trac-Lok will provide greater pulling power by lightly applying the parking brake.

Disassembly

DIFFERENTIAL

1. Remove the housing cover and drain the lubricant.

2. Using an axle spreader tool, mount it onto the axle housing and spread the housing enough to remove the differential.

3. Using a dial indicator, measure the amount the opening is being spread; do not spread the housing more than 0.015 in. (0.38mm), for damage to the housing may occur.

4. Mark the differential bearing caps for reassembly purposes.

5. Loosen the bearing caps until 2–3 threads are engaged.

6. Using a prybar, pry the differential loose.

7. Remove the bearing caps and the differential.

8. Mount the differential into a vise.

9. Remove and discard the ring gear bolts; they are not reusable.

10. Using a brass drift and a hammer, tap the ring gear from the differential.

11. Using a differential bearing puller, press the differential bearings from the differential.

12. Remove the differential bearing shims.

13. Remove the pinion shaft lockpin and pinion shaft.

14. Rotate the pinions to remove them through the case opening.

15. Remove the side gears and thrust washers.

Inspection

If any member of either clutch pack shows evidence of excessive wear or scoring, the complete clutch pack must be replaced on both sides.

1. Thoroughly, clean each part in solvent.

2. Towel dry bearings or allow them to air dry, do not use compressed air to dry bearings as damage might result. Dry all other parts with compressed air or shop towels. If the parts are not to be assembled immediately, cover them to prevent dust or dirt contamination.

3. Inspect the housing for cracks and sand holes. Replace the housing if it is cracked or porous. Check for burrs and deep scratches or nicks on the gasket and oil seal surfaces. An oil stone or fine tooth file may be used to remove nicks or burrs.

4. Inspect the bearing cup bores for nicks or burrs that may have been created during bearing cup removal.

5. Inspect and clean the axle tubes. Inspect the vent to be sure it is not obstructed.

6. Check housing for bent or loose tubes or other physical damage.

7. Inspect the side gears for worn, cracked or chipped teeth. The gears should fit snugly on the axle shaft splines. Also, inspect the fit of the gears in the differential case bore.

Assembly

DIFFERENTIAL

1. Install the side gears, the thrust washers and the pinion gears into the differential case.

NOTE: If new gears and washers are used, it will not be necessary to check the gear backlash. Correct fit is provided due to the close manufacturing tolerances.

2. Install the pinion shaft and lockpin into the case.

3. Assemble the original differential bearing shim packs, then, remove approximately 0.20 in. (0.50mm) shim thickness from each pack; the remaining shims will serve as a starter shim pack.

4. Install the starter shim packs and bearing onto the case.

5. Align and install the ring gear. Using new bolts, torque the ring gear-to-differential case bolts to 100–120 ft. lbs. (136–163 Nm).

6. Install the spreader tool onto the axle housing. Using a dial indicator, spread the axle housing no more than 0.015 in. (0.38mm).

NOTE: Do not spread the housing more than 0.015 in. (0.038mm), for damage may occur to the case.

7. Install the differential; it may be necessary to tap the differential bearing cups, with a soft hammer, to seat them.

Sectional view of the Spicer model 70 Trak-Lok differential

8. Install the differential bearing caps and torque the bolts to 70–90 ft. lbs. (95–122 Nm).

9. Remove the spreader tool and dial indicator.

10. Adjust the ring and pinion gear.

11. Using silicone sealant, apply a bead of it to the axle housing. Install the cover and torque the bolts to 35 ft. lbs. (47 Nm).

FORD MOTOR COMPANY

Front Axle Assembly

DANA—MODEL 28, 44 AND 50 AXLES

Disassembly

DIFFERENTIAL

1. Remove the left axle arm-to carrier case bolts, the left arm and drain the lubricant.

2. Remove the right axle stub shaft by performing the following procedures:

a. Rotate the stub shaft so the open end of the snapping is exposed.

b. Using 2 prybars, force the snapping from the stub shaft.

c. Remove the stub shaft from the carrier.

3. Using an axle spreader tool, mount it onto the axle housing and spread the housing enough to remove the differential.

4. Using a dial indicator, measure the amount the opening is being spread; do not spread the housing more than 0.010 in. (0.25mm), for damage to the housing may occur.

5. Mark the differential bearing caps for reassembly purposes.

6. Loosen the bearing caps until 2–3 threads are engaged.

7. Using a prybar, pry the differential loose.

8. Remove the bearing caps and the differential.

9. Mount the differential into a vise.

10. Remove and discard the ring gear bolts; they are not reusable.

11. Using a brass drift and a hammer, tap the ring gear from the differential.

12. Using a differential bearing puller, press the differential bearings from the differential.

13. Remove the differential bearing shims.

14. Remove the pinion shaft lockpin and pinion shaft.

15. Rotate the pinions to remove them through the case opening.

16. Remove the side gears and thrust washers.

PINION GEAR

1. Remove the differential case from the axle carrier housing.

2. Using a pinion yoke holding tool, remove the pinion gear nut.

3. Remove the pinion washer. Using a pinion yoke holder tool and a pinion puller tool, press the yoke from the pinion gear.

4. Using a soft hammer, drive the pinion gear assembly from the axle carrier housing.

5. Using a bearing cup puller tool and a slide hammer, remove the pinion gear oil seal and discard it. Remove the outer pinion bearing and the oil slinger from the carrier input bore.

6. Remove the pinion bearing preload shims.

7. Using a shop press, press the inner pinion bearing cup and baffle from the bore.

8. Rotate the carrier housing. Using a shop press, press the outer pinion bearing cup from the bore.

9. Using a universal bearing remover tool, press the bearing and the oil slinger from the pinion gear.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

1. Make sure the ring and pinion are a matched set.

2. Perform the depth gauge check, performing the following procedures:

a. Using pinion bearing cup replacer tools and the forcing screw from the depth gauge tool set, install the inner and outer pinion cups.

b. Place a new rear pinion bearing over the aligning adapter and insert it into the pinion bearing retainer assembly. Place the front pinion bearing into the bearing cup in

View of the depth gauge tool set

the carrier and assemble the handle onto the screw and hand tighten.

NOTE: The $\frac{3}{8}$ in. drive in the handle is to be used for obtaining the proper pinion bearing preload.

c. Center the gauge tube into the differential bearing bore. Install the bearing caps and tighten the handle until the bearing preload is 20–40 inch lbs. (2.3–4.5 Nm).

d. Using a feeler gauge or shims, select the thickest feeler shim that will fit between the gauge tube and the gauge block. Insert the feeler gauge or shims directly along the gauge block to insure a correct reading. The feeler gauge, installed between the gauge tube and the gauge block, should have a slight drag feeling.

e. After the correct shims or feeler gauge thickness is obtained, check the reading, this is the thickness of shim(s) required, provided that upon inspection of the service pinion gear, the button is etched 0.

NOTE: If the service pinion gear is marked with a (+) plus reading, this amount must be subtracted from the thickness dimension obtained in step d; example: +2 (–0.002 in.). If the service pinion gear is marked with a (–) minus reading, this amount must be added to the thickness dimension obtained in step d; example: –2 (+0.002 in.). Be sure to use the exact same new rear pinion bearing that was used in the previous steps.

f. Using a micrometer, measure the shims to verify the sizes.

3. Place the oil slinger (if used) onto the pinion. Using a pinion bearing cone installer tool, press the bearing onto the pinion gear.

4. Remove the bearing cup and install the oil baffle (1st) and the required amount of shims into the inner pinion bearing bore.

5. Using the inner pinion bearing cup replacer tool and the forcing screw tool, press the inner pinion bearing

cup; be careful not to cock the cup.

6. Lubricate the ends of the outer pinion bearings rollers with long life lubricant and install the outer bearing cone.

7. Measure the original preload shims and replace with new shims of equal size.

8. Install the pinion into the carrier. Install the shims over the pinion, the outer pinion and oil slinger.

9. Assemble the yoke end, the washer, the deflector and slinger onto the pinion shaft and align.

10. Using a companion flange holder tool, seat the yoke, install a new pinion nut and torque to 175 ft. lbs. (237 Nm) for model 28 or 200-220 ft. lbs. (271-

14. Using a companion flange holder tool, seat the yoke, install a new pinion nut and torque to 175 ft. lbs. (237 Nm) or 200-220 ft. lbs. (271-298 Nm) except for model 28.

DIFFERENTIAL

1. Install the side gears, the thrust washers and the pinion gears into the differential case.

2. Install the pinion shaft and lockpin into the case;peen some differential case metal over the pin to lock it in two places 180 degrees apart.

3. Assemble the ring gear to the differential case and torque the bolts, alternately, to 45-60 ft. lbs. (61-81 Nm).

4. Place the differential assembly into the carrier housing with the master bearings installed.

5. Adjust the pinion and ring gear backlash.

6. Install the right stub shaft by performing the following procedures:

a. Insert the stub shaft into the differential carrier.

b. Position the carrier so the snaping may be installed onto the stub shaft.

c. Using 2 prybars, press the snaping onto the stub shaft.

7. Using silicone sealant, apply a bead of it to the axle housing. Install the cover and torque the bolts to 35 ft. lbs. (47 Nm) except for model 28 or 40-50 ft. lbs. (54-68 Nm) for model 28.

sure the dial indicator returns to zero; repeat this procedure until the dial indicator reading is the same.

NOTE: The reading reveals the amount of shims necessary between the differential case and the differential bearing on the ring gear side.

4. Remove the differential case from the carrier and the master bearings from the case.

5. As determined in step 3, place the required amount of shims onto the ring gear hub of the differential case. Example: if the reading was 0.045 in. (1.14mm), place 0.045 in. (1.14mm) shims onto the hub of the ring gear side of the differential case.

6. Install the bearing cone onto the hub of the ring gear side of the differential case. Using a differential side bearing replacer tool and a shop press, press the bearing onto the hub.

7. To determine the correct amount of shims to be installed on the hub of the drive pinion side, subtract the reading obtained in step 3 from the differential total case endplay. When this amount is determined, add 0.010 in. (0.26mm) to the amount; this is the required amount of shims to be placed on the hub of the drive pinion side of the differential.

Example: Total case endplay was 0.091 in. (2.30mm) and the reading in step 3 was 0.045 in. (1.14mm). Subtract the reading from the endplay; the result is 0.046 in. (1.16mm). Then, add 0.010 in. (0.26mm) to the result; 0.056 in. (1.42mm) is the amount of shims to be added on the hub of the drive pinion side of the differential case.

8. Place the required amount of shims onto the hub of the drive pinion side of the differential case.

9. Install the bearing cone onto the hub of the drive pinion side of the differential case. Using a step plate tool, placed on the ring gear side bearing, and a differential side bearing replacer tool, drive the bearing onto the hub of the drive pinion side of the differential case.

Installing the inner and outer bearing cups—Dana model 44 and 50 front axle assemblies

298 Nm) except for model 28.

11. Using an inch lb. torque wrench, rotate the pinion gear and check the preload; it should be 20-40 inch lbs. (2.25-4.52 Nm).

NOTE: To increase the preload, remove shims; to decrease the preload, install shims.

12. After the preload is adjusted, remove the yoke and washer.

13. Lubricate the pinion oil seal lip. Using an oil seal installation tool, drive a new oil seal into the carrier housing.

Adjustment

PINION AND RING GEAR BACKLASH

1. Install the differential and tighten the bearing caps.

2. Force the differential case away from the drive pinion gear, until it is completely seated against the cross bore face of the carrier. Using a dial indicator, position it so the stylus rests on the differential case bolt and zero the indicator.

3. Force the ring gear against the pinion gear. Rock the ring gear, slightly, to make sure the gear teeth are in contact. Then, force the ring gear away from the pinion gear, making

10. Using a differential bearing replacer tool, install the bearing cone onto the pinion side of the differential case; be sure to position a pinion bearing cone replacer tool on the ring gear bearing to prevent damage to it.

11. Install the differential bearing cups onto the bearing cones.

12. Using a case spreader tool and a dial indicator, spread the carrier housing to 0.015 in. (0.25mm) max.

13. Install the differential case into the carrier; it may be necessary to use a soft hammer to seat the differential case into the carrier-case cross bore.

14. Install the bearing caps; make sure the letters or numbers stamped on the caps correspond in both direction and position with the numbers stamped in the carrier. Torque the bolts to 35–40 ft. lbs. (48–54 Nm) for model 28 or 80–90 ft. lbs. (108–122 Nm) except for model 28.

15. Install a dial indicator to the case and check the ring gear backlash at 3 equally spaced points; the backlash should be 0.005–0.009 in. (0.13–0.23mm) and should not vary more than 0.003 in. (0.08mm) between the points.

NOTE: If the backlash is high, the ring gear must be moved closer to the pinion, by moving the shims from the ring gear side to the opposite side. If the backlash is low, the ring gear must be

moved away from the pinion by moving the shims from the ring gear side to the opposite side.

16. Check and/or adjust the gear tooth pattern.

17. Install the right stub shaft by performing the following procedures:

a. Insert the stub shaft into the differential carrier.

b. Position the carrier so the snapping may be installed onto the stub shaft.

c. Using 2 prybars, press the snapping onto the stub shaft.

18. Using silicone sealant, apply it to the mating surface of the carrier support arm.

NOTE: Allow silicone sealant 1 hour to cure.

19. Using 2 guide pins, assemble the carrier housing to the carrier support arm and torque the new bolts to 30–40 ft. lbs. (41–54 Nm) except for model 28 or 40–50 ft. lbs. (54–68 Nm) for model 28.

20. Except for model 28, install the support arm tab bolt to the side of the carrier and torque the bolts to 85 ft. lbs. (115–136 Nm).

21. For model 28, assemble the carrier shear bolt and nut, then, torque to 75–95 ft. lbs. (102–129 Nm).

DANA 60 MONOBEAM AXLE

The differential side bearing shims are located between the side bearing cup assembly and the differential case. The axle use inner and outer shims on the pinion gear. The inner shims are used to control the pinion depth in the housing, while the outer shims are used to preload the pinion bearings. The axle uses a solid differential carrier with a removable side and pinion gear shaft.

Disassembly

DIFFERENTIAL CARRIER

1. The axle assembly can be overhauled either in or out of the vehicle. Either way, the free-floating axles must be removed.

2. Drain the lubricant and remove the rear cover and gasket.

3. Matchmark the bearing caps and the housing for reassembly in the same position. Remove the bearing caps and bolts.

4. Using a spreader tool mounted to the carrier housing, spread the housing a maximum of 0.015 in.

NOTE: Do not exceed this measurement. The housing could be permanently damaged. The use of a dial indicator is recommended to prevent over-stretching the housing.

Exploded view of the Dana 60 Monobeam front axle differential assembly

Assembled view of the Dana 60 Monobeam front axle assembly

5. Using a pry bar, remove the differential case from the housing. Remove the spreader tool from the housing.

6. Remove the differential side bearing cups and tag to identify the side, if they are to be used again.

7. Remove the differential gear pinion shaft lock pin and remove the shaft. Rotate the side and pinion gears to remove them from the carrier. Remove the thrust bearings.

8. Remove the bearing cones and rollers from the carrier, marking and noting the shim locations.

9. Remove the ring gear bolts and tap the ring gear from the carrier housing.

10. Inspect the components.

DRIVE PINION

1. Remove the pinion nut and flange from the pinion gear.

2. Remove the pinion gear assembly from the housing. It may be necessary to tap the pinion from the housing with a soft faced hammer. Catch the pinion so as not to allow it to drop on the floor.

3. With a long drift, remove the inner bearing cup, pinion seal, slinger, gasket, outer pinion bearing and the shim pack. Label the shim pack for reassembly.

4. Remove the rear pinion bearing cup and shim pack from the housing. Label the shims for reassembly.

5. Remove the rear pinion bearing from the pinion gear with an arbor press and special plates.

Inspection

1. Clean the gears, bearings and component parts with solvent and inspect for scoring, chipping or excessive wear.

2. Inspect the flanges and splines for excessive wear.

3. Replace the necessary parts as required.

PINION SHIM SELECTION

Ring gears and pinions are supplied in matched sets only. The matched numbers are etched on both gears for verification. On the rear face of the pinion, a plus (+) or a minus (-) number will be etched, indicating the best running position for each particular gear set. This dimension is controlled by the shimming behind the inner bearing cup. Whenever baffles or oil slingers are used, they become part of the adjusting shim pack. An example: If a pinion is etched +3, this pinion would require 0.003 in. less shims than a pinion etched 0. This means by removing shims, the mounting distance of the pinion is increased by 0.003 in., which is just what a plus (+) etching indicates. If a pinion is etched -3, it would be necessary to add 0.003 in. more shims than would be required if the pinion was etched 0. By adding the 0.003 in. shims, the mounting distance of the pinion is decreased 0.003 in., which is just what the minus (-) etching indicates. Pinion adjusting shims are available in thicknesses of 0.003 in. (0.08mm), 0.005 in. (0.13mm), 0.010 in. (0.25mm) and 0.030 in. (0.76mm). An example: If a new gear set is used and the old pinion reads +2 and the new pinion reads -2, add 0.004 in. shims to the original shim pack.

Assembly

DRIVE PINION

1. Select the correct pinion depth shims and install in the rear pinion bearing cup bore.

2. Install the rear bearing cup in the axle housing.

3. Add or subtract an equal amount of shim thickness to or from the preload or outer shim pack, as was added or subtracted from the inner shim pack.

4. Install the front pinion bearing cup into its bore in the axle housing.

5. Press the rear pinion bearing onto the pinion gear shaft and install the pinion gear with bearing into the axle housing.

6. Install the preload shims and the front pinion bearing; do not install the oil seal at this time.

7. Install the flange with the holding bar tool attached, the washer and the nut on the pinion shaft end. Torque the nut to 240-300 ft. lbs. (326-406 Nm).

8. Remove the holding bar from the flange and with an inch lb. torque wrench, measure the rotating torque of the pinion gear. The rotating torque should be 10-20 inch lbs. with the original bearings or 20-40 inch lbs. with new bearings. Disregard the torque reading necessary to start the shaft to turn.

9. If the preload torque is not in specifications, adjust the shim pack as required.

a. To increase preload, decrease the thickness of the preload shim pack.

b. To decrease preload, increase the thickness of the preload shim pack.

10. When the proper preload is obtained, remove the nut, washer and flange from the pinion shaft.

11. Install a new pinion seal into the housing and reinstall the flange, washer and nut. Using the holder tool, torque the nut to 240-300 ft. lbs. (326-406 Nm).

DIFFERENTIAL CARRIER

1. Install the differential side gears, the differential pinion gears and new thrust washers into the differential carrier.

2. Align the pinion gear shaft holes and install the pinion shaft into the carrier. Align the lock pin hole in the shaft and carrier. Install the lock pin

Old Pinion Marking	New Pinion Marking								
	-10	-8	-5	-3	0	+3	+5	+8	+10
+10	+.20	+.18	+.15	+.13	+.10	+.08	+.05	+.03	0
+8	+.18	+.15	+.13	+.10	+.08	+.05	+.03	0	-.03
+5	+.15	+.13	+.10	+.08	+.05	+.03	0	-.03	-.05
+3	+.13	+.10	+.08	+.05	+.03	0	-.03	-.05	-.08
0	+.10	+.08	+.05	+.03	0	-.03	-.05	-.08	-.10
-3	+.08	+.05	+.03	0	-.03	-.05	-.08	-.10	-.13
-5	+.05	+.03	0	-.03	-.05	-.08	-.10	-.13	-.15
-8	+.03	0	-.03	-.05	-.08	-.10	-.13	-.15	-.18
-10	0	-.03	-.05	-.08	-.10	-.13	-.15	-.18	-.20

and peen the hole to avoid having the pin drop from the carrier.

3. Install the differential case side bearings with the proper installation tools. Do not install the shims at this time.

4. Place the carrier assembly into the axle housing with the bearing cups on the bearing cones. Install the bearing caps in their original position and tighten the bearing cap bolts enough to keep the bearing caps in place.

5. Install a dial indicator on the housing so the indicator button contacts the carrier flange. Press the differential carrier to prevent sideplay and center the dial indicator. Rotate the carrier and check the flange for run-out. If the run-out is greater than 0.002 in., the defect is probably due to the bearings or to the carrier and should be corrected.

6. Remove the assembly and install the ring gear. Torque the retaining bolts and reinstall the assembly into the housing. Install the bearing caps in their original position and tighten the cap bolts to keep the bearings caps in place.

7. Install the dial indicator and position the indicator button to contact the ring gear back surface. Rotate the assembly and the run-out should be less than 0.002 in. If over 0.002 in., remove the assembly and relocate the ring gear 180 degrees. Reinstall the assembly and recheck. If the run-out remains over the 0.002 in. tolerance, the ring gear is defective. If the measurement is within tolerances, continue on with the assembly.

8. Position 2 pry bars between the bearing cap and the housing on the side opposite the ring gear. Pull on the pry bars and force the differential carrier as far as possible towards the dial indicator. Rock the assembly to seat the bearings and reset the dial indicator to zero.

9. Reposition the prybars to the opposite side of the carrier and force the carrier assembly as far towards the center of the housing. Read the dial indicator scale. This will be the total amount of shims required for setting the backlash during the reassembly, less the bearing preload. Record the measurement.

10. With the pinion gear installed and properly set, position the differential carrier assembly into the axle housing and install the bearing caps in their proper positions. Tighten the cap bolts just to hold the bearing cups in place.

11. Install a dial indicator on the axle housing with the indicator button contacting the back of the ring gear.

12. Position 2 prybars between the

bearing cup and the axle housing on the ring gear side of the case and pry the ring gear into mesh with the pinion gear teeth, as far as possible. Rock the ring gear to allow the teeth to mesh and the bearings to seat. With the pressure still applied by the prybars, set the dial indicator to zero.

13. Reposition the prybars on the opposite side of ring gear and pry the gear as far as it will go. Take the dial indicator reading. Repeat this procedure until the same reading is obtained each time. This reading represents the necessary amount of shims between the differential carrier and the bearing on the ring gear side.

14. Remove the bearing from the differential carrier on the ring gear side and install the proper amount of shims. Reinstall the bearing.

15. Remove the differential carrier bearing from the opposite side of the ring gear. To determine the amount of shims needed, use the following method.

a. Subtract the size of the shim pack just installed on the ring gear side of the carrier from the reading obtained and recorded when measurement was taken without the pinion gear in place.

b. To this figure, add an additional 0.015 in. to compensate for preload and backlash. An example: If the first reading was 0.085 in. and the shims installed on the ring gear side of the carrier were 0.055 in., the correct amount of shims would be $0.085 - 0.055 + 0.015 = 0.045$ in.

16. Install the required shims as determined under step 15 and install the differential side bearing. The installation of the shims should give the proper preload to the bearings and the proper backlash to the ring and pinion gears.

17. Spread the axle housing with the spreader tool no more than 0.015 in. Install the differential bearing outer cups in their correct locations and install the cups in their respective locations.

18. Install the bolts and tighten finger-tight. Rotate the differential carrier and ring gear and tap with a soft-faced hammer to insure proper seating of the assembly in the axle housing.

19. Remove the spreader tool and torque the cap bolts to 80–90 ft. lbs. (108–122 Nm).

20. Install a dial indicator and check the ring gear backlash at 4 equally spaced points of the ring gear circle. The backlash must be within a range of 0.004–0.009 in. and must not vary more than 0.003 in. between the points checked.

21. If the backlash is not within

specifications, the shim packs must be corrected to bring the backlash within limits.

22. Check the tooth contact pattern and verify.

23. Install the cover and torque the bolts to 30–40 ft. lbs. (41–54 Nm). Refill to proper level with lubricant and operate to verify proper assembly.

Rear Axle Assembly

FORD—10¼ AND 8.8 INCH RING GEAR AXLES

Disassembly

DIFFERENTIAL CARRIER

1. Remove the cover and clean the lubricant from the internal parts.

2. Using a dial indicator, measure and record the ring gear backlash and the runout; the backlash should be 0.008–0.015 in. and the runout should be less than 0.004 in.

3. Mark 1 differential bearing cap to ensure it is installed its original position.

4. Loosen the differential bearing cap bolts.

5. Using a prybar, pry the differential carrier until the bearing cups and shims are loose in the bearing caps.

6. Remove the bearing caps and the differential assembly.

7. If necessary, remove ring gear-to-differential case bolts. Using a hammer and a punch, strike the alternate bolt holes around the ring gear to dislodge it from the differential.

8. If necessary, remove the excitor ring by striking it with a soft hammer.

9. Remove the pinion shaft lock bolt from the differential case. Remove the differential pinion shaft, the pinion gears and the thrust washers.

10. Remove the side gears and thrust washers.

11. Using a bearing puller tool, press the bearings from the differential carrier.

PINION GEAR

1. Remove the differential carrier assembly.

2. Using a companion flange holding tool, remove the companion flange nut.

3. Using a puller tool, press the companion flange from the pinion gear.

4. Using a soft hammer, drive the pinion gear from the housing.

5. Using a prybar, remove the pinion gear oil seal from the housing.

6. Remove the oil slinger and the front pinion bearing.

7. Using a shop press, press the

25 DRIVE AXLES DOMESTIC

Exploded view of the 8.8 inch ring gear axle—10.25 inch is similar

bearing cone from the pinion gear.

8. Remove and record the shim from the pinion gear.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

NOTE: When replacing the ring and pinion gear, the correct shim thickness for the new gear set to be installed is determined by following procedure using a pinion depth gauge tool set.

1. Assemble the appropriate aligning adapter, the gauge disc and gauge block to the screw.

2. Place the rear pinion bearing over the aligning tool and insert it into the rear portion of the bearing cup of the carrier. Place the front bearing into the front bearing cup and assemble the tool handle into the screw. Roll the assembly back and forth a few times to seat the bearings while tightening the tool handle, by hand, to 20 ft. lbs. (27 Nm).

NOTE: The gauge block must be offset 45 degrees to obtain an accurate reading.

3. Center the gauge tube into the differential bearing bore. Install the bearing caps and tighten the bolts to 70–85 ft. lbs. (96–115 Nm); be sure to install the caps with the triangles pointing outward.

4. Place the selected shim(s) on the pinion and press the pinion bearing cone and roller assembly until it is firmly seated on the shaft, using the pinion bearing cone replacer and the axle bearing/seal plate.

5. Place the collapsible spacer on the pinion stem against the pinion stem shoulder.

6. Install the front pinion bearing and oil slinger in the housing bore and install the pinion seal on the pinion seal replacer. Using a hammer, install the seal until it seats.

7. From the rear of the axle housing, install the drive pinion assembly into the housing pinion shaft bore.

8. Lubricate the pinion shaft splines and install the companion flange.

9. Using a companion flange holder tool, torque the pinion nut to 160 ft. lbs. (217 Nm); rotate the pinion gear, occasionally, to ensure proper bearing seating.

10. Using an inch pound torque wrench, frequently, measure the pinion bearing preload; it should be 9–14 inch lbs. for used bearings or 16–29 inch lbs. for new bearings.

NOTE: If the preload is higher than the specification, tighten to the original reading as recorded; never back off the pinion nut.

DIFFERENTIAL CARRIER

1. If the bearings were removed, use a shop press to press them onto the differential case.

2. Install the side gears and thrust washers. Install the pinion gears, the thrust washer, the pinion shaft and the pinion shaft lock bolt.

3. Using a shop press, align the excitor ring tab with the differential case slot and press the ring gear and excitor ring onto the differential case. Install the ring gear-to-differential case bolts and torque them to 100–120 ft. lbs. (135–162 Nm).

4. Place the differential case with the bearing cups into the housing.

5. On the left side, install a 0.265 in shim. Install the bearing cap and tighten the bolts finger tight.

6. On the right side, install progressively larger shims until the largest can be installed by hand. Install the bearing cap.

7. Torque the bearing cap-to-housing bolts to 70–85 ft. lbs. (95–115 Nm).

8. Rotate the assembly to ensure free rotation.

9. Adjust the ring gear backlash.

Adjustment

RING GEAR AND PINION BACKLASH

1. Using a dial indicator, measure the ring gear and pinion backlash; it should be 0.008–0.015 in. If the backlash is 0.001–0.007 in. or greater than 0.015 in. proceed to step 3. If the backlash is zero, proceed to step 2.

2. If the backlash is zero, add 0.020 in. shim(s) to the right side and subtract a 0.020 in. shim(s) from the left side.

3. If the backlash is within specification, go to step 7. If the backlash is 0.001–0.007 in. or greater than 0.015 in., increase the thickness of a shim on 1 side and decrease the same thickness of another shim on the other side, until the backlash comes within range.

New of te backlash adjustment by changing shims

4. Install and torque the bearing cap bolts to 80–95 ft. lbs. (109–128 Nm).

5. Rotate the assembly several times to ensure proper seating.

6. Recheck the backlash, if it is not within specification, go to step 7.

7. Remove the bearing caps. Increase the shim sizes, on both sides by 0.006 in.; make sure the shims are fully seated and the assembly turns freely. Use a shim driver to install the shims.

8. Install the bearing caps and torque the bearing caps to 80–95 ft. lbs. (109–128 Nm). Recheck the backlash; if not to specification, repeat this entire procedure.

FORD – 7½ INCH RING GEAR AXLE

Disassembly

DIFFERENTIAL CASE

1. Check and record the ring gear

runout and backlash.

2. Mark on differential bearing cap to help position the caps properly during assembly.

3. Loosen the differential bearing cap bolts and bearing caps.

NOTE: The direction of arrows on bearing caps must be noted. When reassembled, the arrows must be pointing in the same direction as before removal.

4. Pry the differential case, bearing cups and shims out until they are loose in the bearing caps. Remove the bearing caps and the differential assembly from the carrier.

If the ring is removed, discard the bolts. Install new bolts, coated with Loctite® or equivalent. Tighten to 70–85 ft. lbs. (95–115 Nm).

DRIVE PINION

1. Hold the rear axle companion flange with the proper tool and remove the pinion nut.

2. Remove the companion flange. With a soft-faced hammer, drive the pinion out of the front bearing cone and remove it through the rear of the carrier casting.

3. Remove the drive pinion oil seal with tool 1125-AC and T50T-100-A or their equivalent. Remove the front pinion bearing cone, the roller and slinger from the housing.

4. To remove the pinion rear bearing cone, use tool T71P-4621-B or equivalent. Measure the shim found under the bearing cone with a micrometer. Record the thickness of the shim.

NOTE: Before assembling the rear bearing cone to the pinion, it will be necessary to adjust pinion depth.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

.008	.010		

Exploded view of the 7 1/2 inch ring gear axle assembly—Ford Motor Company

Assembly

DRIVE PINION

1. Place the selected shim(s) on the pinion shaft and depress the pinion bearing until firmly seated on the shaft.

2. Place the rear pinion bearing (new or used if in good condition) over the aligning disc and insert it into the pinion bearing cup of the carrier. Place the front bearing into the front bearing cup and assemble the tool handle into the screw and tighten to 20 ft. lbs. (27 Nm).

NOTE: The gauge block must be offset to obtain an accurate reading.

3. Center the gauge tube into the differential bearing bore. Install the bearing caps and torque the bolts to specification; the caps must be installed with the arrows point outboard.

4. Make sure the gauge handle adapter screw, aligning adapter, gauge disc and gauge block assembly are se-

curely mounted between front and rear bearing. Recheck tool handle torque prior to gauging to ensure the bearings are properly seated. This can affect final shim selection when improperly assembled. Clean bearing cups and differential pedestal surfaces thoroughly. Apply only light oil film on bearing assemblies prior to gauging.

5. Gauge block should then be rotated several 1/2 turns to ensure rollers are properly seated in bearing cups. Rotational torque on the gauge assembly should be 20 inch lbs. with new bearings. Final position should be approximately 45 degrees across the gauge tube to ensure the gauge block is aligned with gauge tube high point. This area should be utilized for pinion shim selection. Selection of pinion shim with gauge block not aligned with tube high point will cause improper shim selection and may result in axle noise.

6. Utilize pinion shims as the gauge for shim selection. This will minimize errors in attempting to stack feeler gauge stock together or simple addi-

tion errors in calculating correct shim thickness.

NOTE: Shims must be flat. Do not use dirty, bent, nicked or mutilated shims as a gauge.

7. It is important to utilize a light drag on the shim for the correct selection. Do not attempt to force the shim between the gauge block and gauge tube. This will minimize selection of a shim thicker than required which results in a deep tooth contact in final assembly for integral axles.

8. If the pinion has a plug (+) marking, subtract his amount from the feeler gauge measurement. If the pinion has a minimum (-) marking, add this amount to the feeler gauge measurement.

DIFFERENTIAL CASE

For shim selection after a complete replacement of the rear axle housing, the differential assembly or differential side bearings use the following instructions. For a ring and pinion replacement only or a backlash adjust-

ment, follow Steps 9 through 13 and Step 15, using the side bearing shims that were originally in the axle.

1. With pinion depth set and pinion installed, place differential case gear assembly with bearings and cups into the carrier.

2. Install a 0.265 in. (6.73mm) shim on left side.

3. Install left bearing cap and tighten bolts finger tight.

4. Install progressively larger shims on the right side until the largest shim selected can be assembled with a slight drag feel.

NOTE: Apply pressure towards the left side to ensure bearing cup is seated.

5. Install right side bearing cap and tighten bearing cup bolts to 70–85 ft. lbs. (95–115 Nm).

6. Rotate assembly to ensure free rotation.

7. Check the ring gear and pinion backlash. If the backlash is 0.008–0.015 in. (0.20–0.38mm) with 0.012–0.015 in. (0.304–0.381mm) preferred, proceed to Step 14. If backlash is not within specifications, go to Step 10, unless zero backlash is measured, then, go to Step 8.

8. If a zero backlash conditions occurs, add 0.020 in. to the right side and subtract 0.020 in. from the left side to allow backlash indication.

9. Recheck backlash.

10. If backlash is not to specification, correct backlash by increasing thickness of one shim and decreasing thickness on the other shim the same amount.

11. Install shim and bearing caps. Tighten cap bolts to 70–85 ft. lbs. (95–115 Nm).

12. Rotate assembly several times.

13. Recheck backlash. If backlash is within specification, go to Step 14. If backlash is not within specification, repeat Step 10. Backlash specification is 0.008–0.015 in. (0.20–0.38mm). Preferred range is 0.012–0.015 in. (0.304–0.381mm).

14. Increase both left and right shim sizes by 0.006 in. and install for correct differential bearing preload; make sure shims are fully seated and assembly turns freely.

15. Utilize white marking compound to obtain a tooth mesh contact pattern in the assembly.

NOTE: Pattern inspection is intended to detect gross errors in set up prior to complete reassembly. Pattern contact should be within the primary area of the ring gear tooth surface avoiding any narrow or hard contact with outer perimeter of tooth (top to root, toe to heel). Pattern inspection

Shim changes for ring gear and pinion backlash

tion should be on the drive (pull) side. Correct assembly of drive pattern will result in satisfactory coast performance. If gross pattern error is detected, the preferred backlash of 0.012–0.015 in. (0.30–0.38mm), recheck pinion shim selection.

16. Install bearing caps and tighten cap bolts to 70–85 ft. lbs. (95–115 Nm).

17. Install the axle shafts.

18. Remove the oil seal replacer from the transmission extension housing. Install the driveshaft in the extension housing, align the scribe marks on the flange and driveshaft and connect the driveshaft at the drive pinion flange. Apply Loctite® to the threads of the attaching bolts and torque to 70–95 ft. lbs. (90–128 Nm).

19. Install the brake drum and attaching shakeproof retainers. Install the wheel and tire on the brake drum. Install the wheel covers.

20. Clean the gasket mating surface of the rear axle housing and cover. Apply a new continuous bead of silicone rubber sealant to the carrier casting face.

NOTE: Make sure the machined surfaces on both cover and carrier are clean before installing the new silicone sealant. Inside of axle must be covered when cleaning the machined surface to pre-

vent axle contamination.

21. Install the cover and torque the bolts to 25–35 ft. lbs. (34–47 Nm), except the ratio tag bolt, which is tightened to 15–25 ft. lbs. (20–34 Nm).

NOTE: Cover assembly must be installed within 15 minutes of application of the silicone or new sealant must be reapplied.

22. Add EOAZ-19580-A (ESP-MC2154-A) or equivalent, through the filler hole until the lubricant level is 3/8 in. (9.5mm) below the filler hole with the axle in the running position.

23. Lower vehicle and road test.

Adjustment

DRIVE PINION AND DRIVE PINION BEARING PRELOAD

1. Install the pinion front bearing and slinger.

2. Apply grease, C1AZ-19590-B or equivalent, between the lips of the pinion seal and install the pinion seal.

3. Insert the companion flange into the seal and hold it firmly against the pinion front bearing cone. From the rear of the carrier casting, insert the pinion shaft, with a new spacer, into the flange.

4. Start new pinion nut. Hold the flange with special tool T78P-4851-A or equivalent, and tighten the pinion nut. As the nut is tightened, the pinion

shaft is pulled into the front bearing cone and into the flange.

5. As the pinion shaft is pulled into the front bearing cone, pinion shaft endplay is reduced. While there is still endplay in the pinion shaft, the flange and bearing cone will be felt to bottom on the collapsible spacer.

6. From this point, a much greater torque must be applied to turn the pinion nut, since the spacer must be collapsed. Very slowly, tighten the nut but check the pinion shaft endplay often to see the pinion bearing preload does not exceed the limits.

7. If the pinion nut is tightened to the point that pinion bearing preload exceeds the limits, the pinion shaft must be removed and a new collapsible spacer installed.

NOTE: Do not decrease the preload by loosening the pinion nut. This will remove the compression between the pinion front and rear bearing cones and the collapsible spacer and may permit the front bearing cone to turn on the pinion shaft.

8. As soon as there is a preload on the bearings, turn the pinion shaft in both directions several times to set the bearing rollers.

9. Adjust the bearing preload to specification. Measure the preload.

FORD—9.0 INCH RING GEAR REAR AXLE WITH REMOVABLE CARRIER

Disassembly

DIFFERENTIAL CARRIER

1. Remove the carrier-to-axle housing bolts, the carrier and drain the gear lube.

2. Place the carrier assembly into a holding fixture, check and record the ring gear runout and the ring gear backlash.

3. Mark one of the differential bearing caps and the mating bearing support with punch marks to help position the parts during reassembly of the carrier. Remove the adjusting nut locks, bearing caps, (remove the bearing caps with a soft mallet) and adjusting nuts. Lift the differential case assembly from the carrier.

4. Remove the differential side bearings with special tools T57L-4220-A or T66P-4220-A. Mark the differential case, differential cover and ring gear for assembly in the original position.

5. Separate the differential cover from the differential case. Remove the side gear thrust washer and the side gear. Using a drift, drive out the 3 differential pinion shaft lock pins. Drive out the long differential pinion shaft

with a brass drift.

6. Using a brass drift carefully positioned inside the case, drive out the 2 short differential pinion shafts. Remove the positioning block, differential pinions and the thrust washers from the differential case.

7. Remove the side gear and side gear thrust washer from the case.

8. Position the carrier assembly in a manner that will permit the removal of the drive pinion shaft nut. Remove the companion flange from the drive pinion shaft and remove the pinion seal.

9. Remove the pinion and retainer assembly from the carrier housing. If a new pinion bearing and or gear set is installed, a new shim will have to be installed. Be very careful not to damage the mounting surfaces of the retainer and the carrier.

10. Place a protective sleeve on the pinion pilot bearing surface. Press the pinion shaft out of the pinion retainer. Press the pinion shaft out of the pinion rear bearing cone, using tool T71P-4621-B.

11. Remove and install a new pinion shaft pilot bearing. Remove the old pinion shaft pilot bearing by pressing it off and install the new one by pressing it on. Install a new pinion shaft pilot bearing retainer, concave side up, on the same press.

Exploded view of the 9 in. ring gear axle with a removable carrier—Ford Motor Company

Removing the differential cover

Removing the side gear and thrust washer

Removing the long differential pinion shaft

Removing the short differential pinion shaft

NOTE: Do not remove the drive pinion bearing cups from the retainer unless the cups are worn or damaged or if the cone and roller assemblies are damaged.

12. If the cups are worn or damaged, remove them with the use of bearing cup puller T77F-1102-A or T78P-1225-B or equivalent. Install the new bearing cups by pressing them into the retainer with pinion bearing cup replacer T71P-4616-A or equivalent.

13. After the new cups have been installed, make sure they are seated in the retainer by trying to insert a 0.0015 in. feeler gauge between the cup and the bottom of the bore. Whenever the cups are replaced, the cone and roller assemblies should also be replaced.

DRIVE PINION AND BEARING RETAINER

1. Install a holding fixture onto the flange, then, remove the pinion nut and washer. Leave the holding fixture on the flange and using a puller, remove the flange from the pinion shaft.

2. Using a seal puller, remove the pinion seal from the retainer assembly.

3. Remove the retainer assembly-to-carrier bolts and the carrier. Measure and record the thickness of the shim that was between the retainer and the carrier assembly.

4. Install a piece of hose on the pinion pilot bearing surface in front of the pinion gear. Mount the retainer assembly in a press and press the pinion gear out of the retainer.

5. Mount the pinion shaft in a press and press the rear bearing from the pinion shaft.

6. Mount the retainer assembly into a shop press and press the front and rear bearing cups from the assembly.

7. Using a bearing driver, drive the pilot bearing and retainer out of the carrier assembly.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

DRIVE PINION AND RING GEAR SET

NOTE: When replacing a ring gear and a drive pinion or pinion bearings, select the proper pinion shim thickness by using the following procedure and tool T79P-4020-A or equivalent.

1. Select the proper rear pinion bearing aligning adapter and gauge disc to correspond to the axle size. Slide these adapters over the screw or threaded shaft and install the gauge block on the threaded shaft and tighten it securely.

2. Place this assembly, along with the rear drive pinion bearing, into the pinion bearing retainer assembly. Install the front pinion bearing (new or used, if in good condition) and screw the handle onto the threaded shaft, with the tapered end into the front pinion bearing.

3. The flat end of the handle has a $\frac{3}{8}$ in. square hole broached in it. This is designed so an inch pound torque wrench may be used to obtain the proper pinion bearing preload.

4. Install the pinion bearing retainer assembly into the carrier (without a pinion shim) and tighten the attaching bolts to 30-45 ft. lbs. Rotate the gauge block so it rests against the pilot boss.

5. Place the differential gauge tube into the differential bearing bore and tighten the bearing caps to the specified torque. Using a feeler gauge, gauge the space between the differential bearing gauge block and gauge tube. Insert a feeler blade directly along the gauge block top to ensure a correct reading. The fit should be a slight drag-type feeling.

6. After a correct feeler gauge is obtained, use the conversion chart provided to find the correct shim thickness needed according to the feeler gauge reading.

7. After determining the correct shim thickness as just outlined in this procedure, assemble the pinion bearing retainer as follows.

NOTE: A new ring gear and drive pinion should always be installed in an axle as a matched set, never separately. Be sure the same matching number appears

Proper use of the pinion depth gauge tool

on the ring gear and on the head of the drive pinion.

8. Install the pinion retainer attaching bolts and torque them to 30-45 ft. lbs. Install the oil slinger, if equipped.

9. Install a new pinion oil seal in the bearing retainer, install the companion flange. Start a new pinion nut on the drive pinion shaft and apply a small amount of thread lubricant to the flange side of the nut.

10. Hold the flange with tool T57T-4851-B and tighten the pinion nut: do not use impact tools. Check the pinion bearing preload, the correct preload

Checking the pinion bearing preload

will be obtained when the torque required to rotate the pinion in the retainer is as specified in the specifications.

11. If the torque required to rotate the pinion is less than specified, tighten the pinion shaft nut a little at a time until the proper preload is established.

NOTE: Do not over-tighten the pinion nut. If excessive preload is obtained as a result of over tightening, replace the collapsible bearing spacer. Do not back off the pinion shaft nut to establish pinion bearing preload.

DIFFERENTIAL CARRIER

NOTE: Lubricate all the differential components liberally with hypoid gear lubricant, EOAZ-19580-A or equivalent, during assembly.

1. Place a side gear thrust washer and side gear in the differential case bore. With a soft faced hammer, drive a short differential pinion shaft into the case far enough to retain a pinion thrust washer and pinion gear.

2. Carefully, align the pinion shaft

lock pin holes with the holes provided in the case. Drive a short differential pinion shaft only far enough into the case to retain the pinion thrust washer pinion gear.

3. Install the remaining 2 pinion thrust washers along with the pinion gears into the case. Install the positioning block into the case. Use a soft face hammer, to drive the short differential pinion shafts into the case until the shafts are flush with the side of the case.

4. Insert the long differential pinion shaft and drive it into the case. Be sure the pinion shaft lock holes align with the holes in the case. Place a 2nd side gear and thrust washer into position. Install the 3 pinion shaft lock pins. Press the differential cover on the case.

5. Clean the tapped holes in the ring gear with a suitable solvent. Insert 2- $\frac{7}{16}$ (N.F.) $\times$ 2 bolts through the differential case flange and turn them 3-4 turns into the ring gear as a guide in aligning the ring gear bolt holes. Press or tap the ring gear into position.

6. If the new bolts are coated with a green or yellow coating of approximately $\frac{1}{2}$ in. or over the threaded area, use as is. If it is not coated, apply a suitable thread sealer and torque the bolts to 70-85 ft. lbs; do not reuse the old bolts.

7. If the differential bearings have been removed, press them in using tool T57L-4221-A2 or equivalent. Wipe a thin coating of axle lubricant on the differential bearing bores so the differential bearing cups will move easily.

8. Place the cups on the bearings and set the differential case assembly in the carrier. Assemble the differential case and ring gear assembly in the carrier so the marked tooth on the drive pinion indexes between the marked teeth on the ring gear; be sure to match the marked gears as indicated. When assembled out of time, the result is noise and improper mating.

9. Slide the assembly along the bores until a slight backlash is felt between the gear teeth. Set the adjusting nuts in the bores using differential bearing nut wrench T70P-4067-A so they just contact the bearing cups.

10. The nuts should be engaged about the same number of threads (turns) on each side. Carefully position the differential bearing caps on the carrier. Match the marks made when the caps were removed. Before tightening the bearing cap bolts, be sure the adjuster nuts are properly threaded in the cap and carrier and turn freely.

11. Install the bearing cap bolts and

Exploded view of the differential case

alternately torque them to 70–85 ft. lbs. If the adjusting nuts do not turn freely as the cap bolts are tightened, remove the differential bearing caps and again inspect for damaged threads or incorrectly positioned caps.

12. Tightening the bolts to the specified torque is done to be sure the cups and adjusting nuts are seated. Loosen the cap bolts and tighten them to only 25 ft. lbs. before making adjustments.

13. Adjust the backlash between the ring gear and pinion and the differential bearing preload as described in the following section.

14. Using a new gasket and silicone sealant, position the differential carrier on the studs in the axle housing. Install the carrier-to-housing nuts and washers; torque them to 25–40 ft. lbs.

Adjustment

BACKLASH AND DIFFERENTIAL BEARING PRELOAD

1. Remove the adjusting nut locks, loosen the differential bearing cap bolts and torque the bolts to 15–20 ft. lbs. before making adjustments.

NOTE: The left adjusting nut is on the ring gear side of the carrier and the right nut is on the pinion side.

2. Loosen the right nut until it is away from the cup. Tighten the left nut until the ring gear is just forced into the pinion with zero backlash, then, rotate the pinion several revolutions to be sure there is no binding. Recheck the right nut at this time to make sure it is still loose.

3. Install a dial indicator and tighten the right nut until it first contacts the bearing cups. Set the dial indicator to zero and apply pressure to the bearing by tightening the right nut until the indicator reading shows 0.008–0.012 in. case spread.

4. Turn the pinion gear several times in each direction to seat the bearings in the cups and be sure no bind is evident (this step is important). Tighten the bearing cap bolts to 70–85 ft. lbs.

5. Measure the backlash on several teeth around the ring gear. If the backlash is out of specification, loosen 1 adjusting nut and tighten the opposite nut an equal amount, to move the ring gear away from or toward the pinion.

6. Tightening the left nut moves the ring gear into the pinion to decrease the backlash and tightening the right nut moves the ring gear away.

NOTE: When moving the adjusting nuts, the final movement should always be made in a tightening direction. An example of this is, if the left nut had to be loosened 1 notch, loosen the nut 2 turns and tighten it 1; this ensures the nut is contacting the bearing cup and the cup can not shift after being put in service. After all such adjustments, check to be sure the case spread remains as specified for the new or original bearings used.

7. Use a white marking compound to obtain a tooth mesh contact pattern in the assembly. Pattern contact should be within the primary area of the ring gear tooth surface avoiding any narrow or hard contact with the outer perimeter of tooth (top to root, toe to heel).

8. The pattern inspection should be on the drive (pull) side. The correct assembly of the drive pattern will result in a satisfactory coast performance. If gross pattern error is detected with preferred backlash of 0.012–0.015 in. recheck the pinion shim selection.

DANA—MODEL 30 RING GEAR AXLE

Disassembly

DIFFERENTIAL CARRIER

1. The axle assembly can be overhauled either in or out of the vehicle. Either way, the free-floating axles must be removed.

Location of the pinion shaft lock holes

Typical rear axle pinion depth gauge tool

Exploded view of the Dana model 30 rear axle assembly—Ford Motor Company

2. Drain the lubricant and remove the rear cover and gasket.

3. Matchmark the bearing caps and the housing for reassembly in the same position. Remove the bearing caps and bolts.

4. Using a spreader tool mounted to the carrier housing, spread the housing a maximum of 0.015 in.

NOTE: Do not exceed this measurement. The housing could be permanently damaged. The use of a dial indicator is recommended to prevent over-stretching the housing.

5. Using a pry bar, remove the differential case from the housing. Separate the shims and record the dimensions. Remove the spreader tool from the housing.

6. Remove the differential side bearing cups and tag to identify the side, if they are to be used again.

7. Remove the differential gear pinion shaft lock pin and remove the shaft. Rotate the side and pinion gears to remove them from the carrier. Remove the thrust bearings.

8. Remove the bearing cones and rollers from the carrier, marking and noting the shim locations.

9. Remove the ring gear bolts and tap the ring gear from the carrier housing.

10. Inspect the components.

DRIVE PINION

1. Remove the pinion nut and flange from the pinion gear.

2. Remove the pinion gear assembly from the housing. It may be necessary to tap the pinion from the housing with a soft faced hammer. Catch the pinion so as not to allow it to drop on the floor.

3. With a long drift, remove the inner bearing cup, pinion seal, slinger, gasket, outer pinion bearing and the shim pack. Label the shim pack for reassembly.

4. Remove the rear pinion bearing cup and shim pack from the housing. Label the shims for reassembly.

5. Remove the rear pinion bearing from the pinion gear with an arbor press and special plates.

Inspection

1. Clean the gears, bearings and component parts with solvent and inspect for scoring, chipping or excessive wear.

2. Inspect the flanges and splines for excessive wear.

3. Replace the necessary parts as required.

PINION SHIM SELECTION

Ring gears and pinions are supplied in matched sets only. The matched numbers are etched on both gears for veri-

fication. On the rear face of the pinion, a plus (+) or a minus (-) number will be etched, indicating the best running position for each particular gear set. This dimension is controlled by the shimming behind the inner bearing cup. Whenever baffles or oil slingers are used, they become part of the adjusting shim pack. An example: If a pinion is etched +3, this pinion would require 0.003 in. less shims than a pinion etched 0. This means by removing shims, the mounting distance of the pinion is increased by 0.003 in., which is just what a plus (+) etching indicates. If a pinion is etched -3, it would be necessary to add 0.003 in. more shims than would be required if the pinion was etched 0. By adding the 0.003 in. shims, the mounting distance of the pinion is decreased 0.003 in., which is just what the minus (-) etching indicates. Pinion adjusting shims are available in thicknesses of 0.003, 0.005 and 0.010 in. An example: If a new gear set is used and the old pinion reads +2 and the new pinion reads -2, add 0.004 in. shims to the original shim pack.

Assembly

DRIVE PINION

1. Select the correct pinion depth shims and install in the rear pinion bearing cup bore.

2. Install the rear bearing cup in the axle housing.

3. Add or subtract an equal amount of shim thickness to or from the preload or outer shim pack, as was added or subtracted from the inner shim pack.

4. Install the front pinion bearing cup into its bore in the axle housing.

5. Press the rear pinion bearing onto the pinion gear shaft and install the pinion gear with bearing into the axle housing.

6. Install the preload shims and the front pinion bearing; do not install the oil seal at this time.

7. Install the flange with the holding bar tool attached, the washer and the nut on the pinion shaft end. Torque the nut to 200–220 ft. lbs. (271–298 Nm).

8. Remove the holding bar from the flange and with an inch lb. torque wrench, measure the rotating torque of the pinion gear. The rotating torque should be 10–20 inch lbs. with the original bearings or 20–40 inch lbs. with new bearings. Disregard the torque reading necessary to start the shaft to turn.

9. If the preload torque is not in specifications, adjust the shim pack as required.

a. To increase preload, decrease the thickness of the preload shim pack.

b. To decrease preload, increase the thickness of the preload shim pack.

10. When the proper preload is obtained, remove the nut, washer and flange from the pinion shaft.

11. Install a new pinion seal into the housing and reinstall the flange, washer and nut. Using the holder tool, torque the nut to 200–220 ft. lbs. (271–298 Nm).

DIFFERENTIAL CARRIER

1. Install the differential side gears, the differential pinion gears and new thrust washers into the differential carrier.

2. Align the pinion gear shaft holes and install the pinion shaft into the carrier. Align the lock pin hole in the shaft and carrier. Install the lock pin and peen the hole to avoid having the pin drop from the carrier.

3. Install the differential case side bearings with the proper installation tools. Do not install the shims at this time.

4. Place the carrier assembly into the axle housing with the bearing cups on the bearing cones. Install the bear-

ing caps in their original position and tighten the bearing cap bolts enough to keep the bearing caps in place.

5. Install a dial indicator on the housing so the indicator button contacts the carrier flange. Press the differential carrier to prevent sideplay and center the dial indicator. Rotate the carrier and check the flange for run-out. If the run-out is greater than 0.002 in., the defect is probably due to the bearings or to the carrier and should be corrected.

6. Remove the assembly and install the ring gear. Torque the retaining bolts and reinstall the assembly into the housing. Install the bearing caps in their original position and tighten the cap bolts to keep the bearings caps in place.

7. Install the dial indicator and position the indicator button to contact the ring gear back surface. Rotate the assembly and the run-out should be less than 0.002 in. If over 0.002 in., remove the assembly and relocate the ring gear 180 degrees. Reinstall the assembly and recheck. If the run-out remains over the 0.002 in. tolerance, the ring gear is defective. If the measurement is within tolerances, continue on with the assembly.

8. Position 2 pry bars between the bearing cap and the housing on the side opposite the ring gear. Pull on the pry bars and force the differential carrier as far as possible towards the dial indicator. Rock the assembly to seat the bearings and reset the dial indicator to zero.

9. Reposition the prybars to the opposite side of the carrier and force the carrier assembly as far towards the center of the housing. Read the dial indicator scale. This will be the total amount of shims required for setting the backlash during the reassembly, less the bearing preload. Record the measurement.

10. With the pinion gear installed and properly set, position the differential carrier assembly into the axle housing and install the bearing caps in their proper positions. Tighten the cap bolts just to hold the bearing cups in place.

11. Install a dial indicator on the axle housing with the indicator button contacting the back of the ring gear.

12. Position 2 prybars between the bearing cup and the axle housing on the ring gear side of the case and pry the ring gear into mesh with the pinion gear teeth, as far as possible. Rock the ring gear to allow the teeth to mesh and the bearings to seat. With the pressure still applied by the prybars, set the dial indicator to zero.

13. Reposition the prybars on the opposite side of ring gear and pry the gear as far as it will go. Take the dial indicator reading. Repeat this procedure until the same reading is obtained each time. This reading represents the necessary amount of shims between the differential carrier and the bearing on the ring gear side.

14. Remove the bearing from the differential carrier on the ring gear side and install the proper amount of shims. Reinstall the bearing.

15. Remove the differential carrier bearing from the opposite side of the ring gear. To determine the amount of shims needed, use the following method.

a. Subtract the size of the shim pack just installed on the ring gear side of the carrier from the reading obtained and recorded when measurement was taken without the pinion gear in place.

b. To this figure, add an additional 0.015 in. to compensate for preload and backlash. An example: If the first reading was 0.085 in. and the shims installed on the ring gear side of the carrier were 0.055 in., the correct amount of shims would be $0.085 - 0.055 + 0.015 = 0.045$ in.

16. Install the required shims as determined under step 15 and install the differential side bearing. The installation of the shims should give the proper preload to the bearings and the proper backlash to the ring and pinion gears.

17. Spread the axle housing with the spreader tool no more than 0.015 in. Install the differential bearing outer cups in their correct locations and install the cups in their respective locations.

18. Install the bolts and tighten finger-tight. Rotate the differential carrier and ring gear and tap with a soft-faced hammer to insure proper seating of the assembly in the axle housing.

19. Remove the spreader tool and torque the cap bolts to specifications.

20. Install a dial indicator and check the ring gear backlash at 4 equally spaced points of the ring gear circle. The backlash must be within a range of 0.004–0.009 in. and must not vary more than 0.002 in. between the points checked.

21. If the backlash is not within specifications, the shim packs must be corrected to bring the backlash within limits.

22. Check the tooth contact pattern and verify.

23. Complete the assembly, refill to proper level with lubricant and operate to verify proper assembly.

GENERAL MOTORS CORPORATION

Front Axle Assembly

GMC—8½ INCH RING GEAR AXLE

For overhaul information, refer to the General Motors Corporation 8½ in. ring gear axle, in the rear axle assembly section.

DANA—9¾ INCH RING GEAR AXLE

For overhaul information, refer to the Dana 9¾ in. ring gear axle, in the rear axle assembly section.

GMC—8¼ AND 9¼ INCH RING GEAR AXLE

Disassembly

1. Remove the drain plug and drain the fluid from the axle. Remove the axle from the truck.
2. Measure and record the backlash for it may help to determine the cause of an axle problem.
3. Remove the solenoid and the indicator switch.
4. Remove the right axle tube-to-carrier case bolts and the tube with the shaft.
5. Remove the right output shaft sleeve, the shift shaft, damper spring, shift fork and clip assembly.
6. Remove the inner spring and shim.
7. Clamp the axle shaft tube in a vise, using the mounting flange. Strike the inside of the shaft flange to dislodge the carrier connector. Remove the carrier connector and the retaining ring.
8. On K35 Series, remove the snapping, the washer and the thrust washer from the right axle tube.
9. Remove the right side axle shaft with the deflector.
10. Using pullers J-29362 for 15/25 series or J-J-29369-2 for 35 series, along with J-29307, or their equivalents, remove the seal and bearing from the axle shaft tube.
11. Remove the output shaft.
12. Using a tool J-34011 or equivalent, press the differential pilot bearing.

13. Using a prybar and a soft faced hammer, remove the left side output shaft and deflector.

14. Using a prybar, remove the seal from the axle tube.

15. Using pullers J-29362 for 15/25 series or J-J-29369-2 for 35 series, along with J-29307, or their equivalents, remove the left output shaft bearings from the case.

16. Remove the carrier case bolts, tap on the carrier case lugs and separate the right and left side carrier case halves.

17. Remove the differential assembly. On the right side of K35 series, you'll have to pry up the locks first.

18. On the K35 series, remove the bolt, the lock, the sleeves and the side bearing cups; turn the sleeves to push the cups from the bores.

19. On the K35 series, remove the adjuster plug with the side bearing cup and the O-ring, if equipped, using tool J-36615.

20. Using a holding tool such as J-8614-01, remove the pinion flange nut and washer.

21. Using a pinion flange removal tool, press the pinion flange from the differential.

22. Remove the pinion with the shim, the bearing cone and the spacer, using tool J-36598.

23. Press the spacer from the pinion.

24. Using a bearing removal tool such as J-36598, press the bearing from the pinion.

25. Remove the shim, the seal, the bearing cup and the cone.

26. Using the puller tool, press the bearing cup from the pinion.

27. Remove the side bearings, using tools J-22888-D and J-8107-2 (15/25 series) or J-36597 (35 series).

NOTE: The ring gear bolts are equipped with left handed threads.

28. Remove the ring gear bolts. Using a brass drift, drive the ring gear from the differential case.

29. Using a drift and a hammer, drive the roll pin from the differential case.

30. Remove the retaining bolt (35 series only) and pinion gear shaft.

31. Roll the pinion gears out of the case with their thrust washers.

32. Remove the side gears and their thrust washers.

33. Place identifying marks on the gears and differential case halves.

34. On K35 series, remove the spacer from the carrier.

35. Using a 6-point deep-well socket, remove the vent plug.

36. Drive the carrier bushings out using tool J-36616.

Assembly

PINION BEARING CUP

1. Mount the left case half in a holding fixture such as J-36598. For 15/25 series, use adapter J-36598-6. Tighten the fixture bolts securely.

2. Using J-36598-3 (15/25 series) or J-36598-4 (35 series), install the outer bearing cup.

3. Remove J-36598-3 (15/25 series) or J-36598-4 (35 series), and place J-36598-15 in the pinion seal bore. Extend the forcing screw through the bore.

4. Install J-36598-3 (15/25 series) or J-36598-4 (35 series) on the forcing screw. Turn the forcing screw until the installer is snug against the bearing cup. Rotate the tool several times to make sure it's not cocked in the bore.

5. Pull the inner bearing cup into place in the bore.

PINION DEPTH MEASUREMENT

1. Coat the pinion bearings with axle fluid.

2. Assemble dial indicator J-29763 on gauging tool J-36601-4 (15/25 series) or J-36601-3 (35 series).

3. Install the pinion bearings and hold them in place.

4. Insert the threaded rod of the gauging tool through the bearings.

5. Install the pilot, flat washer and nut on the tool.

6. Tighten the nut while holding the threaded rod. Adjust the nut to obtain a preload of 10-15 inch lbs. Rotate the shaft several times to seat the bearings, then re-measure the torque and adjust as necessary.

7. Push the dial indicator downward until the needle make 3 revolutions and tighten the tool at this position.

8. Place the button of the gauging tool on the differential bearing bore.

9. Rotate the tool, slowly, back and forth, until the dial indicator reads the lowest point in the bore. Set the dial indicator to 0. Repeat, to verify the reading.

10. Hold the gauging arm by its flats and move the tool button out of the bearing bore. Record the dial indicator reading. The reading is equal to the required shim size.

Example: if the reading is 0.508mm, a 0.508 shim is required.

11. Remove the tools and bearing cones.

Pinion Installation

1. Place the proper shim, determined earlier, on the pinion gear.

2. Install the bearing on the pinion gear using J-35512 (15/25 series) or J-36614 (35 series).

3. Place a new spacer on the pinion gear.

4. Place a new seal in the case using J-36266.

5. Place the pinion gear assembly in the case.

6. Install the deflector, flange, washer and nut. Apply sealant, such as PST Sealant® on the pinion gear threads and both sides of the washer.

7. Hold the flange with J-8614-01 and tighten the nut until no endplay is detected. No further tightening should be attempted at this point!

8. Place an inch lbs. torque wrench on the nut and rotate the pinion, observing the reading. The correct preload reading is 15-25 inch lbs.

9. If the reading is low, tighten the nut in very small increments, checking the preload after each tightening. **Do not exceed the recommended preload!** If the recommended preload is exceeded, the pinion will have to be disassembled and a new spacer installed.

10. When the proper preload is set, rotate the pinion several times to make sure the bearings are seated and recheck the preload. Reset, if necessary.

Differential Case

1. On 35 series, install the side gear spacer.

2. Install the thrust washers and side gears in the differential case. On the 35 series, the side gear spacer goes on the left shaft. If used gears and washers are being installed, they must be installed in the same places from which they were removed. Check your identifying marks.

3. Position one pinion gear between the side gears and rotate the gears until the pinion gear is directly opposite the opening in the case.

4. Place the other pinion gear between the side gears, making sure that the holes in the gears line up.

5. Install the thrust washers. Rotate the pinion gears as needed.

6. Install the shaft and pin (15/25 series) or bolt (35 series).

7. Install the ring gear using **new** bolts. Never reuse old bolts! Using an alternating sequence, torque the bolts in 3 progressive steps, to a maximum torque of 88 ft. lbs.

8. Using tools J-22761 (15/25 series) or J-29710 (35 series), along with J-8092, install the side bearings.

9. Using tools J-8092 and J-36612 (15/25 series) or J-36613 (35 series) install the carrier bearings on the sleeves or adjuster plug (35 series).

10. On the 35 series, install a new O-ring on the adjuster plug.

11. On 15/25 series, install the sleeves in the carrier case using J-36599.

12. On 35 series, install the right sleeve using J-36599; install the adjuster plug using J-36615.

13. Using J-36602 and J-8092, install the side bearing cups.

14. Place the differential assembly in the carrier case half containing the pinion gear assembly.

Turn the left sleeve (15/25 series) or adjuster plug (35 series) inward until backlash is felt between the ring and pinion.

15. Remove the case from the holding fixture.

16. Join the case halves **without using sealer at this time**. If the case halves do not mate completely, back out the right sleeve until they do. Tighten the bolts to 35 ft. lbs.

BACKLASH ADJUSTMENT

1. Tighten the right sleeve to 100 ft. lbs.

2. Tighten the left sleeve (15/25 series) or adjuster plug (35 series) to 100 ft. lbs.

3. Matchmark the sleeves and/or plug and the case so that the notches can be counted when turned.

4. Turn the right sleeve **out 2** notches.

5. Turn the left sleeve or adjuster plug **in 1** notch.

6. Rotate the pinion several times to seat the bearings.

7. Install indicator and fixture J-34047-3, J-34047-1 and J-8001-1 in the filler plug hole so the stem of the indicator is at the heel end of a tooth.

8. Check and record the backlash at 3 or 4 points around the gear. The pinion must be held stationary while checking backlash. The backlash should be the same at each point $\pm 0.05\text{mm}$. If the backlash varies more than $\pm 0.05\text{mm}$, check for burrs, a distorted case flange, uneven bolt torques or foreign matter.

Gear backlash should be 0.08-0.25mm with a preferred setting of 0.13-0.18mm.

9. If backlash is incorrect, adjust the sleeves and/or plug as necessary. Follow this example: If it is necessary to turn the right sleeve **in 1** notch, turn the left sleeve or plug **out 1** notch.

To increase backlash, turn the left sleeve or plug **in** and the right sleeve **out** an identical amount.

To decrease backlash turn the right sleeve **in** and the left sleeve or plug **out** an identical amount.

A 1 notch change will cause an 0.08mm change in backlash.

GEAR PATTERN CHECK

Before final assembly of the differential, a pattern check of the gear teeth must be made. This determines if the teeth of the ring and pinion gears are

meshing properly, for low noise level and long life of the gear teeth. The most important thing to note is if the pattern is located centrally up and down on the face of the ring gear.

1. Wipe any oil from the carrier and all dirt and oil from the teeth of the ring gear.

2. Coat the teeth of the ring gear with a gear marking compound.

3. Apply a load until it takes 40-50 ft. lbs. of torque to turn the pinion gear.

4. Turn the companion flange so the ring gear makes a full rotation in 1 direction, then, turn it a full rotation in the opposite direction.

5. Check the pattern on the teeth and refer to the chart for any adjustments necessary. Contact pattern can be adjusted by either a change in the pinion depth or a change in backlash. Adjust the pattern as necessary.

Carrier Case

1. Bend the locks over the sleeves.

2. Install the bolt and lock over the adjuster plug on the 35 series.

3. Remove the bolts and lift off the right case half.

4. Thoroughly clean the case half mating surfaces with a solvent such as carburetor cleaner.

5. Apply a bead of Loctite®518, or equivalent, on the mating surface of either carrier half. Install the right half and torque the bolts to 35 ft. lbs.

6. Install the left seal, driving it into place with a seal driver and hammer.

7. Drive the shaft and deflector into place.

8. Using J-33842, install the bearing on the output shaft.

9. Install the output shaft in the carrier.

10. Install the vent plug, using Loctite®518 on the threads.

11. Using J-36616, install the carrier bushings.

Axle Tube

1. Drive the bearing into the tube.

2. Install a new seal.

3. Install the shaft and deflector in the tube.

4. Install the washer, aligning the tabs with the slots in the tube.

5. Install the connector gear and retaining ring into place with a plastic mallet.

6. Install the washer and a new snapping (35 series). Make sure that the snapping is fully seated.

7. If any of the following components were replaced, it will be necessary to select the proper size output shaft shim:

- Output shaft
- Tube

- Outer shaft
- Carrier case
- Ring and pinion
- Differential case
- Side bearings
- Connector

a. Push outward on the inner end of the outer shaft and move the shaft outward as far as it will go. The shaft must remain in this position for all measurements.

b. On 15/25 series, measure between the tube flange machined end and the inner surface of the connector. Record the distance.

On 35 series, measure between the tube flange machined surface and the inner surface of the axle shaft shoulder. Record the distance.

This figure is distance "A".

d. On all models, measure the distance between the carrier machined surface and the outer surface of the output shaft. Record the distance. This figure is distance "B".

e. Subtract distance "A" from distance "B". The correct shim size will be one size smaller than the resultant figure. For example: If the resultant figure was 3.53mm, the necessary shim will be 3.30mm.

If the resultant figure was 3.30mm, the necessary shim will be 2.70mm (15/25 series) or 2.80mm (35 series).

Shims are available in the following sizes:

- 15/25 series — 1.27mm, 1.78mm, 2.29mm, 2.70mm, 3.30mm, 3.81mm
- 35 series — 1.80mm, 2.30mm, 2.80mm, 3.30mm, 3.80mm, 4.30mm, 4.80mm

Final Assembly

1. Install the shim selected above on the output shaft. Use grease to hold it in place.

2. Install the sleeve.

3. Install the spring.

4. Install the shift shaft, spring, shift fork and clip in the case. The damper spring fits into the fork indentation. Make sure the clip is seated in the groove on the shift shaft.

5. Apply a bead of Loctite®518 on the tube mating surface and assemble the tube and carrier. Torque the bolts to 30 ft. lbs.

6. Using a brass drift, reach through the actuator hole and manually operate the shift mechanism. The mechanism should move smoothly, without binding.

7. Apply Loctite®518 on the solenoid threads. Tighten the solenoid to 16 ft. lbs.

8. Apply Loctite®518 on the switch threads. Tighten the switch to 45 inch lbs.

9. Refill the axle and install the filler plug and washer. Torque the plug to 24 ft. lbs.

Rear Axle Assembly

The rear axles are categorized by the ring gear diameter and are identified as follows: 7½, 8½, 9½ in. (GMC) semi-floating axles; 9¾, 10½ in. (Dana) full floating axles; 10½ in. (GMC) full floating axles and 12 in. (Rockwell) full floating axles.

GMC—7½ INCH RING GEAR AXLE

Disassembly

REAR AXLE CASE

1. Before removing the rear axle case from the housing, check the ring gear-to-drive pinion backlash. This will indicate gear or bearing wear or an error in backlash or preload setting which will help in determining cause of axle noise.

2. Mark the bearing caps **R** and **L** to make sure they will be reassembled in their original location. Remove rear axle bearing cap bolts.

3. Remove rear axle case. Exercise caution in prying on carrier so the gasket sealing surface is not damaged. Place right and left bearing outer races and shims in sets with marked bearing caps so they can be reinstalled in their original positions.

4. If rear axle side bearings are to be replaced, use a puller to remove them.

5. Remove rear axle pinions, side gears and thrust washers from case. Mark the side gear and case after removing bolts. Using a brass drift and hammer, drive it off; do not pry between ring gear and case.

DRIVE PINION, BEARING AND RACES

1. Check drive pinion bearing preload. If there is no preload reading, check for looseness of pinion assembly by shaking. Looseness could be caused by defective bearings or worn pinion flange. If rear axle was operated for an extended period with very loose bear-

ings, the ring gear and drive pinion will also require replacement.

2. Remove pinion flange nut and washer.

3. Remove pinion flange.

4. Install a drive pinion remover tool and drive out pinion. Apply heavy hand pressure on the pinion remover toward rear axle housing to keep front bearing seated to avoid damage to outer race.

NOTE: The rear pinion bearing must be removed when it becomes necessary to change the pinion depth adjustment.

5. With drive pinion removed from carrier, press bearing from the pinion gear.

6. Drive pinion oil seal from carrier and remove front pinion bearing. If this bearing is to be replaced, remove outer race from carrier.

7. If rear pinion bearing is to be replaced, remove outer race from carrier using a punch in slots provided for this purpose.

Cleaning and Inspection

1. Clean all rear axle bearings thoroughly in clean solvent (do not use a brush). Examine bearings visually and by feel. All bearings should feel smooth when oiled and rotated while applying as much hand pressure as possible. Minute scratches and pits appear on rollers and races at low mileage are due to the initial preload and bearings having these marks should not be rejected.

2. Examine sealing surface of pinion flange for nicks, burrs or rough tool marks which would cause damage to the seal and result in an oil leak. Replace if damaged.

3. Examine carrier bore and remove any burrs that might cause leaks around the O.D. of the pinion seal.

4. Examine the ring gear and drive pinion teeth for excessive wear and scoring. If any of these conditions exist, replacement of the gear set will be required.

5. Inspect the pinion gear shaft for unusual wear; also check the pinion and side gears and thrust washers.

6. Check the press fit of the side bearing inner race on the rear axle case hub by prying against the shoulder at the puller recess in the case. Side bearings must be a tight press fit on the hub.

7. Diagnosis of a rear axle failure such as: chipped bearings, loose (lapped-in) bearings, chipped gears, etc., is a warning that some foreign material is present; therefore, the axle housing must be cleaned.

Checking the pinion pre-load

Assembly**DRIVE PINION**

1. If a new rear pinion bearing is to be installed, install new outer races.
2. If a new front pinion bearing is to be installed, install new outer race.

NOTE: Pinion depth is set with pinion setting gauge. The pinion setting gauge provides in effect, a normal or zero pinion as a gauging reference. Instructions are included in gauge set.

3. Make certain all of the gauge parts are clean.

4. Lubricate front and rear pinion bearings liberally with rear axle lubricant.

5. While holding bearings in position, install depth setting gauge assembly.

6. Hold stud stationary with a wrench positioned over the flats on the ends of stud and tighten nut to 20 inch lbs. (2.2 Nm) torque. Rotate gauge plate assembly several complete revolutions to seat the bearings. Tighten nut until a torque between 15–25 inch lbs. (1.6–2.2 Nm) is obtained to keep the gauge plate in rotation.

7. Rotate the gauge plate tool until the gauging areas are parallel with the discs.

8. Make certain rear axle side bearing support bores are clean and free of burrs.

9. Install the correct discs on the gauge shaft.

10. Position the gauge shaft assembly in the carrier so the dial indicator rod is centered on the gauging area of the gauge block and the discs seated fully in the side bearing bores. Install side bearing caps and torque bolts to 55 ft. lbs. (75 Nm). Use a dial indicator reading from 0.00–100.0 inch (0.0–2.5mm).

11. Set dial indicator at zero. Then position on mounting post of the gauge shaft with the contact button touching the indicator pad. Push dial indicator downward until the needle rotates approximately $\frac{3}{4}$ turn clockwise. Tighten the dial indicator in this position and recheck.

12. Rotate gauge shaft slowly back and forth until the dial indicator reads the greatest deflection. At the point of greatest deflection, set the dial indicator to zero. Repeat rocking action of gauge shaft to verify the zero setting.

13. After the zero setting is obtained, rotate gauge shaft until the dial indicator rod does not touch the gauge block.

14. Record dial reading at pointer position. Example: If pointer moved counterclockwise 0.067 in. (1.70mm) to a dial reading of 0.033 in. (0.84mm) except as follows: dial indicator read-

Checking the pinion depth

ing should be within the range of 0.50–0.020–0.050 in. (1.27mm).

15. Loosen the stud tool and remove gauge plate, washer and both bearings from carrier.

16. Position correct shim on drive pinion and install the drive pinion rear bearings.

REAR AXLE CASE

Before assembling the rear axle case, lubricate all parts with rear axle lubricant.

1. Place side gear thrust washer over side gear hubs and install side gears in case. If same parts are reused, install in original sides.

2. Position one pinion, without washer, between the side gears and rotate gears until pinion is directly opposite from loading opening in case. Place other pinion between side gears so the pinion shaft holes are in line; then, rotate gears to make sure holes in pinions align with the holes in case.

3. If the holes align, rotate pinions back toward loading opening just enough to permit sliding in pinion thrust washers.

4. After making certain the mating surfaces of case and ring gear are clean and free of burrs, thread 2 bolts into opposite sides of ring gear; then, install ring gear on case. Install new ring gear attaching bolts snug; never reuse old bolts. Torque bolts alternately in progressive stages to 90 ft. lbs. (120 Nm).

5. If case side bearings were removed, reinstall bearings.

NOTE: The side bearing preload adjustment is to be made before installing the pinion.

6. If the pinion is installed, remove ring gear. Case side bearing preload is adjusted by changing the thickness of

both the right and left shims by an equal amount. By changing the thickness of both shims equally, the original backlash will be maintained. Pro-

Installing the case side bearings

duction shims are cast iron and vary in thickness from 0.210–0.272 in. (5.33–6.91mm) in increments of 0.002 in. (0.05mm). Standard service spacers are 0.170 in. (4.32mm) thick and steel service shims are available from 0.040–0.082 in. (1.02–2.08mm) in increments of 0.002 in. (0.05mm).

NOTE: Do not attempt to reinstall the production shims as they may break when tapped into place. If service shims were previously installed, they can be reused but, whether using new or old bearings, adhere to the following procedure in all cases.

7. Before installing of the case assembly, make sure the side bearing surfaces in the carrier are clean and free of burrs. If the same bearings are

4.32mm (.170") SERVICE SPACER

Total Thickness of Both Prod. Shims Removed	Total Thickness of Service Shims to be Used as a Starting Point
10.57mm .420"	1.52mm .060"
10.92mm .430"	1.78mm .070"
11.18mm .440"	2.03mm .080"
11.43mm .450"	2.29mm .090"
11.68mm .460"	2.54mm .100"
11.94mm .470"	2.79mm .110"
12.19mm .480"	3.05mm .120"
12.45mm .490"	3.30mm .130"
12.70mm .500"	3.56mm .140"
12.95mm .510"	3.81mm .150"
13.21mm .520"	4.06mm .160"
13.46mm .530"	4.32mm .170"
13.97mm .550"	4.83mm .190"

being reused, they must have the original outer races in place.

8. Determine the approximate thickness of shims needed by measuring each production shim or each service spacer and shim pack.

9. In addition to the service spacer, a service shim will be needed. To select a starting point in service shim thickness, use the following chart.

10. Place case with bearing outer races in position in carrier. Slip the service spacer between each bearing race and carrier housing with chamfered edge against housing.

NOTE: Install the left bearing cap loose so the case may be moved while checking adjustments. Another bearing cap bolt can be added in the lower right bearing cap hole. This will prevent case from dropping while making shim adjustments.

11. Select 1 or 2 shims totaling the amount shown in the right-hand column and position between the right bearing race and the service spacer. Be sure left bearing race and spacer are against left side of housing.

12. Insert progressively larger feeler gauge sizes 0.010 in. (0.25mm), 0.012 in. (0.30mm), 0.014 in. (0.36mm) or etc. between the right shim and service spacer until there is noticeable increased drag. Push the feeler gauge downward until the end of the gauge makes contact with the carrier bore so as to obtain a correct reading. The point just before additional drag begins is correct feeler gauge thickness. Rotate case while using feeler gauge to assure an even reading.

NOTE: The original light drag is caused by weight of the case against the carrier while addi-

tional drag is caused by side bearing preload. By starting with a thin feeler gauge, a sense of feel is obtained so the beginning of preload can be recognized to obtain zero clearance. It will be necessary to work case in and out and to the left in order to insert the feeler gauge.

13. Remove left bearing cap and shim from carrier. The total shim pack needed (with no preload on side bearings) is the feeler gauge reading in step 12 plus thickness of shims installed in step 10.

14. Select 2 shims of approximately equal size whose total thickness is equal to the value obtained in Step 12. These shims will be installed between each side bearing race and service spacer when the case is installed in the carrier.

NOTE: The objective is to obtain the equivalent of a slip fit of the case in the carrier. For convenience in setting backlash, the preload will not be added until the final step.

15. If the pinion is in position, install the ring gear and adjust the rear axle backlash.

DRIVE PINION, BEARING AND RACES

1. Install a new collapsible spacer on pinion and position assembly in carrier. Lubricate the pinion bearings with rear axle lubricant before installing pinion.

2. Hold the pinion forward in the case assembly.

3. Install the front bearing onto pinion and the drive bearing onto pinion shaft until sealed in the race.

4. Position and install the pinion oil seal in the carrier.

5. Lubricate the pinion oil seal lips and seal surface of pinion flange. Install pinion flange on pinion by tapping with a soft hammer until a few pinion threads project through the flange.

6. Install the pinion washer and nut. While holding the pinion flange, intermittently, rotate the pinion to seat pinion bearings. Tighten the pinion flange nut until the endplay begins to disappear. When no further endplay is detectable and the holder will no longer pivot freely as the pinion is rotated, the preload specifications are being approached; no further tightening should be attempted until the preload has been checked.

7. Check the preload by using an inch lb. torque wrench. After the preload has been checked, final tightening should be done very carefully.

NOTE: If when checking, preload was found to be 5 inch lbs. (0.6 Nm), any additional tightening of the pinion nut can add many additional inch lbs. of torque. Therefore, the pinion nut should be further tightened only a little at a time, for the preload specifications will compress the collapsible spacer too far and require the installation of a new collapsible spacer.

8. While observing the preceding note, carefully set preload at 24–32 inch lbs. (2.7–3.6 Nm) on new bearings or 8–12 inch lbs. (1.0–1.4 Nm) for used bearings.

9. Rotate pinion several times to assure the bearings have been seated. Check the preload again, if preload has been reduced by rotating pinion, reset preload to specifications.

Adjustment

REAR AXLE BACKLASH

1. Install rear axle case into carrier, using shims as determined by the side bearing preload adjustment.

2. Rotate the rear axle case several times to seat bearings, then, mount a dial indicator. Use a small button on the indicator stem so contact can be made near heel end of tooth. Set the dial indicator so the stem is aligned as nearly as possible with gear rotation and perpendicular to tooth angle for accurate backlash reading.

3. Check the backlash at 3 or 4 points around ring gear. Lash must not vary more than 0.002 in. (0.05mm) around ring gear. The pinion must be held stationary when checking backlash; if variation is greater than 0.002 in. (0.05mm) check for burrs, uneven bolting conditions or distorted case flange and make corrections, as necessary.

4. Backlash at the point of minimum lash should be between 0.005–0.009 in. (0.13–0.23mm) for all new gears.

5. If backlash is not within specifications, correct by increasing thickness of one shim and decreasing thickness of other shim the same amount. This will maintain correct rear axle side bearing preload.

a. For each 0.001 in. (0.03mm) change in backlash desired, transfer 0.002 in. (0.05mm) in shim thickness.

b. To decrease backlash 0.001 in. (0.03mm), decrease thickness of right shim 0.002 in. (0.05mm) and increase thickness of left shim 0.002 in. (0.05mm).

c. To increase backlash 0.002 in. (0.05mm), increase thickness of right shim 0.004 in. (0.10mm) and decrease thickness of left shim 0.004 in. (0.10mm).

6. When the backlash is correctly adjusted, remove both bearing caps and both shim packs. Keep the packs in their respective position, right or left side. Select a shim 0.004 in. (0.10mm) thicker than the one removed from left side, then, insert left side shim pack between the spacer and the left bearing race. Loosely install bearing cap.

7. Select a shim 0.004 in. (0.10mm) thicker than the one removed from right side and insert between the spacer and the right bearing race; it will be necessary to drive the right shim into position.

8. Torque to 55 ft. lbs. (75 Nm).

9. Recheck backlash and correct if necessary.

10. Install the axles.

11. Install a new cover gasket, the cover and torque the bolts to 20 ft. lbs. (27 Nm).

12. Refill the rear axle to the proper level.

GMC—8½ AND 9½ INCH RING GEAR AXLE

This axle assembly is the semi-floating type with a hypoid type drive pinion and ring gears. The drive pinion gear is supported by 2 bearings. The differential case contains 2 pinion gears. The carrier assembly is not removable since it is part of the axle assembly but the design allows for the differential assembly to be serviced while the axle is still in the vehicle. The ring gear bolted to a one piece differential case is supported by 2 preloaded roller bearings.

Disassembly

DIFFERENTIAL CASE

1. Remove the inspection cover from the axle housing and drain the gear lubricant into a pan.

2. Remove the screw or pin that holds the pinion shaft in place and remove the shaft.

3. Push the axle shaft(s) in a little and remove the C-locks from the ends of the shafts. Remove the axle shafts from the housing.

4. Measure and record the backlash; this will allow the old gears to be reassembled at the same amount of lash to avoid changing the gear tooth pattern. It also helps to indicate if there is gear or bearing wear and if there is any error in the original backlash setting.

5. Remove the differential pinions, the side gears and thrust washers from the case; be sure to mark the pinions and side gears so they may be reassembled in their original position.

6. Mark the bearing caps and housing and loosen the retaining bolts. Tap the caps lightly to loosen them. When the caps are loose, remove the bolts and reinstall them, just a few turns; this will keep the case from falling out of the housing when it is pried loose.

7. Using a pry bar, carefully, pry the case assembly loose; be careful not to damage the gasket surface on the housing when prying. The case assembly may suddenly come free if the bearings were preloaded, so pry very slowly.

8. When the case assembly is loose, remove the bearing cap bolts and the caps. Place the caps so they may be reinstalled in the same position. Place any shims that were removed with the cap.

9. Using a bearing puller, pull the differential bearing from the case.

10. To remove the drive pinion bearing, perform the following procedures:

a. Depending on the bearing that is being replaced, remove the front or rear bearing cup from the carrier assembly.

b. With the pinion gear mounted in a press, press the rear bearing from the pinion shaft. Be sure to record the thicknesses of the shims that were removed from between the bearing and the gear.

DRIVE PINION

1. With the differential removed, check the pinion preload. Do this by checking the amount of torque needed to turn the pinion gear. For a new bearing, it should be 20–25 inch lbs. and for a used bearing it should be 10–15 inch lbs. If there is no preload reading check the pinion for looseness. If there is any looseness, replace the bearing.

2. Using a holder assembly to secure the flange, remove the flange nut and washer.

3. Using a puller, press the flange from the pinion splines.

4. Thread the pinion nut, a few turns, onto the pinion shaft. Using a brass drift and hammer, lightly tap the end of the pinion shaft to remove the pinion from the carrier; be careful not to allow the pinion to fall out of the carrier.

5. With the pinion removed from the carrier, discard the old seal pinion nut and collapsible spacer; install new ones when reassembling.

RING GEAR

1. Remove the ring gear-to-differential case bolts and tap the ring gear from the case with a soft hammer.

Cross-sectional view of the General Motors 8½ and 9½ inch rear axle assembly

25 DRIVE AXLES DOMESTIC

NOTE: Do not try to pry the ring gear off the case. This will damage the machined surfaces.

2. Clean all dirt from the case assembly and lubricate the case with gear lube.

Cleaning and Inspection

1. Clean all parts in solvent and blow dry.

2. Check all of the parts for any signs of wear, chips, cracks or distortion; replace any parts that are defective.

3. Check the fit of the differential side gears in the case and the fit of the side gear and axle shaft splines.

Assembly

DRIVE PINION BEARING

1. Using a bearing driver, install a new bearing cup for each one that was removed; make sure the cups are seated fully against the shoulder in the housing.

2. The pinion depth must be checked to determine the nominal setting. This allows for machining variations in the housing and enables selection of the proper shim so the pinion depth can be set for the best bear tooth contact.

3. Clean the housing and carrier assemblies to insure accurate measurement of the pinion depth.

4. Lubricate the front and rear pinion bearings with gear lubricant and install them in their races in the carrier assembly.

5. Using a pinion setting gauge, select the proper clover leaf plate and install it on the preload stud.

6. Using the proper pilot, insert the stud through the rear bearing, with the proper size pilot on the stud and through the front bearing. Install the hex nut and tighten it until it is snug.

7. Using a wrench to hold the preload stud, torque the hex nut until 20 inch lbs. of torque are required to rotate the bearings.

8. Install the side bearing discs on the ends of the arbor assembly, using the step of the disc that fits the bore of the carrier.

9. Install the arbor and plunger assembly into the carrier; make sure the side bearing discs fit properly.

10. Install the bearing caps in the carrier assembly finger tight; make sure the discs do not move.

11. Mount a dial indicator on the mounting post of the arbor with the contact button resting on the top surface of the plunger.

13. Preload the dial indicator by turning it 1/2 revolution and tightening it in this position.

14. Use the button on the gauge plate that corresponds to the ring gear size and turn the plate so the plunger rests on top of it.

15. Rock the plunger rod back and forth across the top of the button until the dial indicator reads the greatest amount of variation. Set the dial indicator to zero at the point of most variation. Repeat the rocking of the plunger several times to check the setting.

16. Turn the plunger until it is removed from the gauge plate button. The dial indicator will now read the pinion shim thickness required to set the nominal pinion depth; record the reading.

17. Check for the pinion code number, located on the rear face of the pinion gear; the number will indicate the necessary change to the pinion shim thickness.

NOTE: If the pinion is marked with a plus (+) and a number, add that much to the reading of the dial indicator. If the pinion has no mark, use the reading from the dial indicator as the correct shim thickness. If the pinion is marked with a minus (-) and a number, subtract that amount from the reading on the dial indicator.

Gauge tools installed in the carrier

18. Remove the depth gauge tools from the carrier assembly and install the proper size shim on the pinion gear.

19. Lubricate the bearing with gear lubricant and use a shop press to press the bearing onto the pinion shaft.

DRIVE PINION

1. Lubricate the front bearing and install it into the front cup.

2. Using a seal driver and a gauge plate, drive the pinion seal into the bore until the gauge plate is flush with the shoulder of the carrier.

3. Lubricate the seal lips and install a new bearing spacer on the pinion gear.

EXAMPLE

RING GEAR SIDE		OPPOSITE SIDE	
.250"	Thickness of Tool J-22779 required to force ring gear into contact with pinion	Combined total of: Service Spacer (A) Service Shim (B) Feeler Gauge (C)	.265"
-.010" .240"	TO MAINTAIN PROPER BACKLASH (.005" - .008"), ring gear is moved away from pinion by subtracting .010" shims from ring gear side and adding .010" shims to other side		+.010" .275"
+.004"	TO OBTAIN PROPER PRELOAD on side bearings, add .004" shims to each side.		+.004"
.244"	Shim dimension required for ring gear side	Shim dimension required for opposite side	.279"

Shim pack selection chart

4. Install the pinion gear into the carrier assembly. Using a large washer and nut, draw the pinion gear through the front bearing, far enough to install the companion flange.

5. With the companion flange installed on the pinion shaft, use a holder assembly and tighten the pinion nut until all of the endplay is removed from the drive pinion.

6. When no more endplay exists, check the preload; the preload should be 20–25 inch lbs. on new bearings or 10–15 inch lbs. on used bearings. Tighten the pinion nut until these figures are reached; do not over tighten the pinion, for this will collapse the spacer too much and make it necessary to replace it.

7. Turn the pinion gear several times to make sure the bearings are seated and recheck the preload.

RING GEAR

1. Align the ring gear bolt holes with the carrier holes and lightly press the ring gear onto the case assembly.

2. Install the bolts and tighten them all evenly, using a criss-cross pattern to avoid cocking the ring gear.

3. When the ring gear is firmly seated against the case, torque the bolts to 60 ft. lbs.

DIFFERENTIAL CASE ASSEMBLY

1. Place the new differential bearing onto the case hub with the thick side of the inner race toward the case. Using a bearing driver, drive the bearing onto the case until it seats against the shoulder on the case.

2. Install the thrust washers and side gears into the case assembly. If the original parts are being used, be sure to place them in their original position.

3. Place the pinions in the case so they are 180 degrees apart as they engage the side gears.

4. Turn the pinion gears so the case holes align with the gear holes. When the holes are aligned, install the pinion shaft and lock screw; do not tighten the lock screw too tightly at this time.

5. Check the bearings, bearing cups, cup seat and carrier caps to make sure they are in good condition.

6. Lubricate the bearings with gear lube. Install the cups on the bearings and the differential assembly into the carrier. Support the carrier assembly to keep it from falling.

7. Install a support strap on the left side bearing and tighten the bearing bolts to an even, snug fit.

8. With the ring gear tight against the pinion gear, insert a gauge tool between the left side bearing cup and the carrier housing.

9. While lightly shaking the tool back and forth, turn the adjusting

wheel until a slight drag is felt and tighten the locknut.

10. Between the right side bearing and carrier, install a 0.170 in. thick service spacer, a service shim and a feeler gauge. The feeler gauge must be thick enough so a light drag is felt when it is moved between the carrier and the shim.

11. Add the total of the service spacer, service shim and the feeler gauge. Remove the gauge tool from the left side of the carrier, then, using a micrometer, measure the thickness in at least 3 places. Average the readings and record the result.

12. Refer to the chart to determine the proper thickness of the shim packs.

13. Install the left side shim first, then, the right side shim between the bearing cup and spacer. Position the shim so the chamfered side is facing outward or next to the spacer.

NOTE: If there is not enough chamfer around the outside of the shim, file or grind the chamfer a little to allow for easy installation.

14. If there is difficulty in installing the shim, partially remove the case from the carrier and slide both the shim and case back into place.

15. Install the bearing caps and torque them to 60 ft. lbs. Tighten the pinion shaft lock screw.

NOTE: The differential side bearings are now preloaded. If any adjustments are made in later procedures, make sure not to change the preload. Do not change the total thickness of the shim packs.

16. Mount a dial indicator on the carrier assembly with the indicator button perpendicular to the tooth angle and aligned with the gear rotation.

17. Measure the amount of backlash between the ring and pinion gears; it should be between 0.005–0.008 in. Take readings at 4 different spots on the gear; there should not be variations greater than 0.002 in.

18. If there are variations greater than 0.002 in. between the readings, check the runout between the case and ring gear; the gear runout should not be greater than 0.003 in. If the runout exceeds 0.003 in., check the case and ring gear for the deformation or dirt between the case and gear.

19. If the gear backlash exceeds 0.008 in., increase the thickness of the shims on the ring gear side and decrease the thickness of the shims on the opposite side, an equal amount.

20. If the backlash is less than 0.005 in., decrease the shim thickness on the

Checking the gear tooth contact

ring gear side and increase the shim thickness on the opposite side an equal amount.

GEAR PATTERN CHECK

Before final assembly of the differential, a pattern check of the gear teeth must be made. This determines if the teeth of the ring and pinion gears are meshing properly, for low noise level and long life of the gear teeth. The most important thing to note is if the pattern is located centrally up and down on the face of the ring gear.

1. Wipe any oil from the carrier and all dirt and oil from the teeth of the ring gear.

2. Coat the teeth of the ring gear with a gear marking compound.

3. With the bearing caps torqued to 55 ft. lbs., expand the brake shoes until it takes 20–30 ft. lbs. of torque to turn the pinion gear.

4. Turn the companion flange so the ring gear makes a full rotation in 1 direction, then, turn it a full rotation in the opposite direction.

5. Check the pattern on the teeth and refer to the chart for any adjustments necessary.

6. With the gear tooth pattern checked and properly adjusted, install the axle housing cover gasket and cover and tighten securely. Refill the axle with gear lube to the correct level.

7. Road test the vehicle to check for any noise and proper operation of the rear.

GMC—10½ INCH RING GEAR AXLE

This axle is a full floating type that uses special hypoid type drive and pinion gears. The pinion gear is supported by 3 bearings, 2 in front of the pinion gear and 1 behind. The differential assembly has either 2 or 4 pinions depending on the application of the axle. This axle assembly must be removed from the vehicle to remove and service the differential.

Cross-sectional view of the General Motors 10½ inch rear axle

Disassembly

DIFFERENTIAL

1. Place the axle assembly in a vise or holding fixture.
2. Remove the cover bolts, the cover and allow the gear lubricant to drain into a pan.
3. Remove the axle shafts from the axle assembly.

NOTE: Measure and record the pinion backlash so if the same gears are reused they may be installed at the same backlash to avoid changing the gear tooth pattern.

4. From the bearing caps, remove the adjusting nut lock retainers.
5. Mark the bearing caps so they may be reinstalled in the same position and remove the bearing caps.
6. Loosen the side bearing adjusting nut and remove the differential carrier from the axle housing.

PINION

1. Remove the differential assembly from the axle.

2. Check the pinion bearing for the proper preload. The force required to turn the pinion should be 25–35 inch lbs. for used bearings. If there is no reading, shake the companion flange to check for any looseness in the bearing. If there is any looseness present, replace the bearing.

3. Remove the pinion bearing retainer-to-axle housing bolts.

4. Remove the bearing retainer and pinion assembly from the axle housing. It may be necessary to tap the pilot end of the pinion shaft to help remove the pinion assembly from the carrier.

5. Record the thickness of the shims that are removed from between the carrier assembly and the bearing retainer assembly.

DRIVE PINION

1. With the pinion assembly clamped in a vise, install a holder assembly on the flange.
2. Using the proper size socket, remove the pinion nut and washer from the pinion.

NOTE: When reassembling the pinion use a new nut and washer assembly.

3. With the holder assembly still in place, use a puller to remove the flange from the pinion.

4. With the bearing retainer supported in a shop press, press the pinion out of the retainer assembly; be careful not to allow the pinion gear to fall onto the floor because this can damage the gear.

5. Separate the pinion flange, the oil seal, the front bearing and the bearing retainer; if the oil seal needs to be replaced it may have to be driven from the retainer.

6. Using a drift, drive the front and rear bearing cups from the bearing retainer.

7. Support the pinion assembly in a press, with the bearing supported. Press the bearing from the pinion gear.

8. Using a drift, drive the straddle bearing from the carrier assembly.

DIFFERENTIAL CASE

1. Scribe a line across both halves of the differential case so they may be reassembled in the same position and with the ring gear removed, separate the halves.

2. Remove the ring gear bolts and washers; using a soft hammer tap the ring gear from the case.

3. Remove the internal parts from the case and set them aside in order so they may be reassembled in the same position.

4. If removing the side bearing, perform the following procedures:

- a. Install a bearing puller on the bearing and press the bearing assembly from the differential case.
- b. Check the bearings for any signs of wear or distortion.

Cleaning and Inspection

1. Clean all of the parts in solvent and blow dry.

2. Check the differential gears, pinions, thrust washers and spider for any signs of unusual wear, chips, cracks or pitting.

3. Check the pinion gear for signs of wear, chips, cracks or any other imperfections. Check the splines for signs of wear or distortion.

4. Check all mating surfaces for signs of wear.

5. Check the bearings for signs of wear or pitting on the rollers and races and check the bearing cage for dents and bends. Check the bearing retainer for any cracks, pits, grooves or corrosion.

6. Check the pinion flange splines for any signs of wear or distortion.

7. Replace parts that show any of the signs mentioned above.

Assembly

DIFFERENTIAL CASE

1. If the side bearing was removed, perform the following procedures:

a. Install a new bearing on the differential case.

b. Using a bearing driver, drive the bearing onto the case assembly until it seats against the shoulder on the case.

2. Using a good quality gear lubricant coat all of the parts.

3. Assemble the differential pinions and thrust washers onto the spider and install the assembly into the differential case.

4. Align the scribe marks on both halves of the differential case and install the ring gear.

5. Install the ring gear washers and bolts and torque the bolts to approx. 10 ft. lbs.

DRIVE PINION

1. Coat all of the parts with a good quality gear lubricant.

2. Position the pinion gear into a shop press and press the rear bearings onto the pinion assembly.

3. Using a bearing driver, install the front and rear bearing cups into the bearing retainer.

4. Using a bearing driver, install the straddle bearing assembly in the axle housing.

5. Install the bearing retainer, with the bearing cups, onto the pinion gear and install a new collapsible spacer.

6. Using a shop press, press the front bearing onto the pinion gear.

7. Lubricate the oil seal with a good quality high pressure grease and install the seal into the retainer bore; be sure to press the seal until it rests against the internal shoulder.

8. Install the pinion flange and oil deflector onto the pinion gear splines, then, install a new lock washer and pinion nut.

9. With the pinion flange clamped in a vise and a holder assembly installed on the flange, tighten the nut to obtain the proper preload; 25-35 inch lbs. for a new bearing or 5-15 inch lbs. for a used bearing. To preload the bearing, tighten the pinion nut to approx. 350 ft. lbs. and take a reading of the torque required to turn the pinion. Continue tightening the nut until the proper preload is obtained.

NOTE: Do not tighten the nut too tightly because it will collapse the spacer too much. This will make replacement necessary.

DRIVE PINION

1. If installing a new pinion gear, check the top of the new gear for the depth code number.

2. Compare the new number with the old number on top of the old pinion and check the pinion depth chart for preliminary setting of the pinion depth.

3. Check the thickness of the original shims removed from the pinion and either add or subtract from the shims according to the chart.

4. Place the shim on the carrier assembly and align the holes with those in the axle housing; make sure the surfaces are clean of all dirt and grease.

5. Install the retainer and pinion assembly in the housing making sure the holes align. Install the retaining bolts and torque to approx. 45 ft. lbs.

DIFFERENTIAL CASE

1. Place the bearing cups over the side bearings on the differential assembly and place the unit into the carrier in the axle housing.

2. Align the marks and install the bearing caps and the bolts. Tighten the bearing retaining bolts.

3. Loosen the right side nut and tighten the left side nut until the ring gear comes in contact with the pinion gear; do not force the gears together. This brings the gears to zero lash.

4. Back off the left side adjusting nut about 2 slots and install the lock fingers into the nut.

5. In this order, tighten the right side adjusting nut firmly to force the case assembly into tight contact with the left side adjusting nut, then, loosen the right side nut until it is free from the bearing.

6. Again, retighten the right side adjusting nut until it comes in contact with the bearing. Tighten the right adjusting nut about 2 slots for an old bearing or 3 slots for a new bearing.

7. Install the lock retainers into the slots and torque the bearing cap bolts to 100 ft. lbs.; this procedure now insures the bearings are preloaded properly. If more adjustments are made, make sure the preload stays the same.

		CODE NUMBER ON ORIGINAL PINION				
		+2	+1	0	-1	-2
CODE NUMBER ON SERVICE PINION	+2	---	ADD .001	ADD .002	ADD .001	ADD .004
	+1	SUBT. .001	---	ADD .001	ADD .002	ADD .003
	0	SUBT. .002	SUBT. .001	---	ADD .001	ADD .002
	-1	SUBT. .003	SUBT. .002	SUBT. .001	---	ADD .001
	-2	SUBT. .004	SUBT. .003	SUBT. .002	SUBT. .001	---

Pinion depth codes and corresponding shim thicknesses

To do this, 1 adjusting nut must be loosened the same amount the other nuts is tightened.

8. Install a dial indicator on the housing and measure the amount of backlash between the ring and pinion gear. The backlash should measure between 0.003-0.012 in. with the best figure being between 0.005-0.008 in.

9. If the backlash is more than 0.012 in., loosen the right side adjusting nut 1 slot and tighten the left side 1 slot. If the backlash is less than 0.003 in., loosen the left side nut 1 slot and tighten the right side 1 slot. These adjustments should bring the backlash measurement into an acceptable range.

PATTERN CHECK

1. Clean all the oil from the ring gear. Using a gear marking compound, coat the teeth of the ring gear.

2. Make sure the bearing caps are torqued to 110 ft. lbs. and apply load to the gears while rotating the pinion. Rotate the ring gear a full turn in both directions.

NOTE: Load must be applied to the assembly while rotating or the pattern will not show completely.

3. Check the pattern on the ring gear, adjust the assembly to get the contact pattern located centrally on the face of the ring gear teeth.

DANA-9¾ AND 10½ INCH RING GEAR AXLES

The Dana Corporation's 9¾ and 10½ in. ring gear axle assemblies are basically the same but with certain exceptions. The differential side bearing shims are located between the side bearing cup assembly and the differential case on the 9¾ in. ring gear axle assembly, while on the 10½ in. ring gear axle assembly, the side bearing shims are located between the side bearing cup and the axle housing. Both axles use inner and outer shims on the pinion gear. The inner shims are used to control the pinion depth in the housing, while the outer shims are used to preload the pinion bearings. The 9¾ in. ring gear axle uses a solid differential carrier with a removable side and pinion gear shaft. The 10½ in. ring gear axle uses a split differential carrier with the side and pinion gears mounted on a cross shaft.

Disassembly

DIFFERENTIAL CARRIER

9¾ Inch

1. The axle assembly can be overhauled either in or out of the vehicle.

25 DRIVE AXLES DOMESTIC

Exploded view of the Dana 9 $\frac{3}{4}$ Inch differential assembly

Exploded view of the Dana 10 $\frac{1}{2}$ Inch differential assembly

Either way, the free-floating axles must be removed.

2. Drain the lubricant and remove the rear cover and gasket.

3. Matchmark the bearing caps and the housing for reassembly in the same position. Remove the bearing caps and bolts.

4. Using a spreader tool mounted to the carrier housing, spread the housing a maximum of 0.015 in.

NOTE: Do not exceed this measurement. The housing could be permanently damaged. The use of a dial indicator is recommended to prevent over-stretching the housing.

5. Using a pry bar, remove the differential case from the housing. Separate the shims and record the dimensions and location on the 10½ in. ring gear axle. Remove the spreader tool from the housing.

6. Remove the differential side bearing cups and tag to identify the side, if they are to be used again.

7. Remove the differential gear pinion shaft lock pin and remove the shaft. Rotate the side and pinion gears to remove them from the carrier. Remove the thrust bearings.

8. Remove the bearing cones and rollers from the carrier, marking and noting the shim locations.

9. Remove the ring gear bolts and tap the ring gear from the carrier housing.

10. Inspect the components.

10½ Inch

1. The axle assembly can be overhauled either in or out of the vehicle. Either way, the free-floating axles must be removed.

2. Drain the lubricant and remove the rear cover and gasket.

3. Matchmark the bearing caps and the housing for reassembly in the same position. Remove the bearing caps and bolts.

4. Using a spreader tool mounted to the carrier housing, spread the housing a maximum of 0.015 in.

NOTE: Do not exceed this measurement. The housing could be permanently damaged. The use of a dial indicator is recommended to prevent over-stretching the housing.

5. Using a pry bar, remove the differential case from the housing. Separate the shims and record the dimensions and location on the 10½ in. ring gear axle. Remove the spreader tool from the housing.

6. Using puller tools, press the differential side bearings from the case.

7. Remove the ring gear bolts and tap the ring gear from the case with a soft-faced hammer.

8. Matchmark the case halves for reassembly and remove the retaining bolts.

9. Tap the upper case ½ to separate it from the bottom ½. Remove the internal gears, washers and cross.

DRIVE PINION

1. Remove the pinion nut and flange from the pinion gear.

2. Remove the pinion gear assembly from the housing. It may be necessary to tap the pinion from the housing with a soft faced hammer. Catch the pinion so as not to allow it to drop on the floor.

3. With a long drift, remove the inner bearing cup, pinion seal, slinger,

gasket, outer pinion bearing and the shim pack. Label the shim pack for reassembly.

4. Remove the rear pinion bearing cup and shim pack from the housing. Label the shims for reassembly.

5. Remove the rear pinion bearing from the pinion gear with an arbor press and special plates.

Inspection

1. Clean the gears, bearings and component parts with solvent and inspect for scoring, chipping or excessive wear.

2. Inspect the flanges and splines for excessive wear.

3. Replace the necessary parts as required.

SIDE BEARING SHIM SELECTION

10½ Inch

1. With the pinion gear not in the axle housing, place the bearing cups over the side bearings and install the differential carrier into the axle housing.

2. Place the shim that was originally installed on the ring gear side into its original position.

3. Install the bearing caps in their proper positions and tighten the bolts to keep the bearings in place.

4. Mount a dial indicator on the axle housing with the indicator button contacting the back of the ring gear.

5. Position 2 prybars between the bearing shim and the housing on the ring gear side of the differential carrier. Force the differential carrier away from the dial indicator and set the indicator to zero.

6. Reposition the prybars to the opposite side of the differential carrier

- 2	+ 0.002	+ 0.001	0	- 0.001	- 0.002	- 0.003	- 0.004	- 0.005	- 0.006
- 3	+ 0.001	0	- 0.001	- 0.002	- 0.003	- 0.004	- 0.005	- 0.006	- 0.007
- 4	0	- 0.001	- 0.002	- 0.003	- 0.004	- 0.005	- 0.006	- 0.007	- 0.008

and force the carrier back towards the dial indicator. Repeat several times until the same reading is obtained each time.

7. To the dial indicator reading, add the thickness of the shim and record the results to be used later in the assembly.

PINION SHIM SELECTION

Ring gears and pinions are supplied in matched sets only. The matched numbers are etched on both gears for verification. On the rear face of the pinion, a plus (+) or a minus (-) number will be etched, indicating the best running position for each particular gear set. This dimension is controlled by the shimming behind the inner bearing cup. Whenever baffles or oil slingers are used, they become part of the adjusting shim pack. An example: If a pinion is etched +3, this pinion would require 0.003 in. less shims than a pinion etched 0. This means by removing shims, the mounting distance of the pinion is increased by 0.003 in., which is just what a plus (+) etching indicates. If a pinion is etched -3, it would be necessary to add 0.003 in. more shims than would be required if the pinion was etched 0. By adding the 0.003 in. shims, the mounting distance of the pinion is decreased 0.003 in., which is just what the minus (-) etching indicates. Pinion adjusting shims are available in thicknesses of 0.003, 0.005 and 0.010 in. An example: If a new gear set is used and the old pinion reads +2 and the new pinion reads -2, add 0.004 in. shims to the original shim pack.

Assembly

DRIVE PINION

1. Select the correct pinion depth shims and install in the rear pinion bearing cup bore.

2. Install the rear bearing cup in the axle housing.

3. Add or subtract an equal amount of shim thickness to or from the preload or outer shim pack, as was added or subtracted from the inner shim pack.

4. Install the front pinion bearing cup into its bore in the axle housing.

5. Press the rear pinion bearing onto the pinion gear shaft and install the pinion gear with bearing into the axle housing.

6. Install the preload shims and the front pinion bearing; do not install the oil seal at this time.

7. Install the flange with the holding bar tool attached, the washer and the nut on the pinion shaft end. Torque the nut to 250 ft. lbs. for the 10½ in. and 255 ft. lbs. for the 9¾ in.

8. Remove the holding bar from the flange and with an inch lb. torque wrench, measure the rotating torque of the pinion gear. The rotating torque should be 10-20 inch lbs. with the original bearings or 20-40 inch lbs. with new bearings. Disregard the torque reading necessary to start the shaft to turn.

9. If the preload torque is not in specifications, adjust the shim pack as required.

a. To increase preload, decrease the thickness of the preload shim pack.

b. To decrease preload, increase the thickness of the preload shim pack.

10. When the proper preload is obtained, remove the nut, washer and flange from the pinion shaft.

11. Install a new pinion seal into the housing and reinstall the flange, washer and nut. Using the holder tool, torque the nut to 250 ft. lbs. for the 10½ in. and 255 ft. lbs. for the 9¾ in.

DIFFERENTIAL CARRIER

9¾ Inch

1. Install the differential side gears, the differential pinion gears and new thrust washers into the differential carrier.

2. Align the pinion gear shaft holes and install the pinion shaft into the carrier. Align the lock pin hole in the shaft and carrier. Install the lock pin and peen the hole to avoid having the pin drop from the carrier.

3. Install the differential case side bearings with the proper installation tools. Do not install the shims at this time.

4. Place the carrier assembly into the axle housing with the bearing cups on the bearing cones. Install the bearing caps in their original position and tighten the bearing cap bolts enough to keep the bearing caps in place.

5. Install a dial indicator on the housing so the indicator button contacts the carrier flange. Press the differential carrier to prevent sideplay and center the dial indicator. Rotate the carrier and check the flange for run-out. If the run-out is greater than 0.002 in., the defect is probably due to the bearings or to the carrier and should be corrected.

6. Remove the assembly and install the ring gear. Torque the retaining bolts and reinstall the assembly into the housing. Install the bearing caps in their original position and tighten the cap bolts to keep the bearings caps in place.

7. Install the dial indicator and position the indicator button to contact the ring gear back surface. Rotate the assembly and the run-out should be

less than 0.002 in. If over 0.002 in., remove the assembly and relocate the ring gear 180 degrees. Reinstall the assembly and recheck. If the run-out remains over the 0.002 in. tolerance, the ring gear is defective. If the measurement is within tolerances, continue on with the assembly.

8. Position 2 pry bars between the bearing cap and the housing on the side opposite the ring gear. Pull on the pry bars and force the differential carrier as far as possible towards the dial indicator. Rock the assembly to seat the bearings and reset the dial indicator to zero.

9. Reposition the prybars to the opposite side of the carrier and force the carrier assembly as far towards the center of the housing. Read the dial indicator scale. This will be the total amount of shims required for setting the backlash during the reassembly, less the bearing preload. Record the measurement.

10. With the pinion gear installed and properly set, position the differential carrier assembly into the axle housing and install the bearing caps in their proper positions. Tighten the cap bolts just to hold the bearing cups in place.

11. Install a dial indicator on the axle housing with the indicator button contacting the back of the ring gear.

12. Position 2 prybars between the bearing cup and the axle housing on the ring gear side of the case and pry the ring gear into mesh with the pinion gear teeth, as far as possible. Rock the ring gear to allow the teeth to mesh and the bearings to seat. With the pressure still applied by the prybars, set the dial indicator to zero.

13. Reposition the prybars on the opposite side of ring gear and pry the gear as far as it will go. Take the dial indicator reading. Repeat this procedure until the same reading is obtained each time. This reading represents the necessary amount of shims between the differential carrier and the bearing on the ring gear side.

14. Remove the bearing from the differential carrier on the ring gear side and install the proper amount of shims. Reinstall the bearing.

15. Remove the differential carrier bearing from the opposite side of the ring gear. To determine the amount of shims needed, use the following method.

a. Subtract the size of the shim pack just installed on the ring gear side of the carrier from the reading obtained and recorded when measurement was taken without the pinion gear in place.

b. To this figure, add an additional 0.015 in. to compensate for pre-

load and backlash. An example: If the first reading was 0.085 in. and the shims installed on the ring gear side of the carrier were 0.055 in., the correct amount of shims would be $0.085 - 0.055 + 0.015 = 0.045$ in.

16. Install the required shims as determined under step 15 and install the differential side bearing. The installation of the shims should give the proper preload to the bearings and the proper backlash to the ring and pinion gears.

17. Spread the axle housing with the spreader tool no more than 0.015 in. Install the differential bearing outer cups in their correct locations and install the cups in their respective locations.

18. Install the bolts and tighten finger-tight. Rotate the differential carrier and ring gear and tap with a soft-faced hammer to insure proper seating of the assembly in the axle housing.

19. Remove the spreader tool and torque the cap bolts to specifications.

20. Install a dial indicator and check the ring gear backlash at 4 equally spaced points of the ring gear circle. The backlash must be within a range of 0.004–0.009 in. and must not vary more than 0.002 in. between the points checked.

21. If the backlash is not within specifications, the shim packs must be corrected to bring the backlash within limits.

22. Check the tooth contact pattern and verify.

23. Complete the assembly, refill to proper level with lubricant and operate to verify proper assembly.

10½ Inch

1. Install new thrust washers to the side gears and lubricate the contact surfaces.

2. Assemble the side gears, pinion bears, washers and cross shaft into the flanged case ½.

3. Install the upper case ½ to the bottom ½, making sure the scribe marks are aligned.

4. Install the retaining bolts finger tight, then, torque the bolts alternately.

5. If a new ring gear is to be installed or the old one used, install it to the differential case and align the bolt holes and torque the bolts alternately.

6. Install the side carrier bearings.

7. Install the differential carrier, with the side bearings and cups installed, in place in the axle housing.

8. Select the smallest of the original shims as a gauge shim and place it between the bearing cup and the housing on the ring gear side.

9. Install the bearing caps and tighten the bolts to hold the cups in place.

10. Mount a dial indicator on the ring gear side of the axle housing and position the indicator button on the rear side of the ring gear.

11. Position 2 prybars between the bearing cup and the housing on the side opposite the ring gear. With the prybars, force the differential carrier towards the dial indicator and set the indicator dial to zero.

12. Reposition the prybars on the ring gear side of the carrier and force the ring gear into mesh with the pinion gear while observing the dial indicator reading. Repeat this operation until the same reading is obtained each time.

13. Add this indicator reading to the gauging shim thickness to determine the correct shim dimension for installation on the ring gear side of the differential carrier.

14. An example: If the gauging shim was 0.115 in. and the indicator reading was 0.017 in., the correct shim would be $0.115 + 0.017 = 0.172$ in.

15. Remove the gauge shim and install the correct shim into position between the bearing cup and the axle housing on the ring gear side of the housing.

16. To determine the correct dimension for the remaining shim, refer to the side bearing shim selection for the 10½ in. and obtain the recorded shim size. From that figure, subtract the size of the shim installed in step 14 and add 0.006 in. for the bearing preload and backlash.

17. An example: If the reading of the shim just installed on the ring gear side of the carrier was 0.172 in. and the reading obtained during the checking of clearance without the pinion installed was 0.329, the correct shim dimension would be as follows: $0.329 - 0.172 = 0.157 + 0.006 = 0.163$ in.

18. Spread the axle housing with a spreader tool, no more than 0.015 in. The carrier assembly is in place in the housing.

19. Assemble the shim, as determined previously, into place between the bearing cup and the housing. Remove the spreader tool.

20. Install the bearing caps in their marked positions and torque the bolts to specifications.

21. Install a dial indicator and check the ring gear backlash at 4 equally spaced points around the ring gear.

22. The backlash must be within 0.004–0.009 in. and must not vary more than 0.002 in. between the positions checked.

23. Whenever the backlash is not within the allowable limits, it must be corrected. Changing of the shim packs is required.

a. Low backlash is corrected by decreasing the shim on the ring gear

side and increasing the opposite side shim an equal amount.

b. High backlash is corrected by increasing the shim on the ring gear side and decreasing the opposite side shim an equal amount.

24. Check the tooth contact pattern and correct as required.

25. Complete the assembly, refill to the correct level and operate to verify correct repairs.

ROCKWELL—12 INCH RING GEAR AXLE

Disassembly

DIFFERENTIAL

1. Remove locknut, adjusting screw and thrust block.

2. Remove 2 adjuster lock cap screws and locks.

3. Punch-mark bearing caps and carrier to help in locating caps for assembly. Remove bearing adjusters and bearing caps.

NOTE: Do not pry caps free with a prybar or distort locating dowels.

4. Carefully remove differential assembly from carrier.

5. Use a differential side bearing remover to pull bearing cones off each side of case.

6. Make sure the differential case halves are punch-marked so they can be reassembled in same position.

7. Remove drive gear and separate case halves.

8. Remove 2 side gears, the differential spider and the 4 differential pinions.

9. Remove pinion and side gear thrust washers.

DRIVE PINION

1. Remove seal retainer and gasket from carrier.

2. Using brass drift against inner end of pinion, drive out the pinion and bearing assembly.

3. Remove shim pack from carrier from those models having tapered roller outer bearings.

4. It may be necessary to use a drift to remove the pinion rear bearing.

5. Clamp yoke in soft-jawed vise. Remove yoke nut and washer and separate drive pinion from yoke.

6. Separate yoke from oil seal retainer.

7. Place retainer in a soft-jawed vise and, using a hammer and chisel, remove oil seal and then the felt oil seal.

8. If equipped with a tapered roller outer bearing, remove bearing cup, outer tapered bearing cone and bearing spacer from drive pinion.

9. Using a bearing remover press plate with shop press, press the bearing cone or roller bearing from the drive pinion.

10. If equipped, remove the bearing lock ring and use press plates with shop press to press the roller bearing from inner end of drive pinion.

Inspection

1. Clean the gears, bearings and component parts with solvent and inspect for scoring, chipping or excessive wear.

2. Inspect the flanges and splines for excessive wear.

3. Replace the necessary parts as required.

Assembly

NOTE: Thoroughly, clean and lubricate all components with axle lubricant before reassembling.

DRIVE PINION

1. Clean counterbore of oil seal retainer. Saturate the felt seal in oil and install evenly in retainer. Soak oil seal in light engine oil for about 1 hour before installing. Coat outer surface of seal lightly with sealing compound to prevent oil leaks between seal and retainer.

2. Install oil seal into retainer with lip of seal toward inner side of retainer. Using a seal installer, press oil seal into retainer with face of seal flush with retainer face.

3. Retainer surface must be clean and smooth to prevent oil leaks between retainer and carrier.

4. Using a shop press, press bearing into place into carrier bore or the roller bearing into position on drive pinion with chamfered side of inner race facing toward pinion shoulder. Position bearing lock ring to secure bearing on drive pinion.

NOTE: Opposed tapered roller bearing cones, 2 bearing cups and spacer are serviced and replaced as a unit. The spacer is a preselected one to provide proper bearing adjustment.

5. Models with tapered roller bearings:

a. Press inner bearing cone into place with largest side of cone facing the pinion gear end.

b. Install original shim pack in carrier. If original ring gear and pinion are reinstalled, use shims that were removed. Shims are available in 5 thicknesses: 0.012, 0.015, 0.018, 0.021 and 0.024 in. When using new

gears, start with a 0.021 in. shim and check the pinion depth.

c. Insert the pinion assembly into carrier, align roller bearing with carrier boss. Install bearing spacer, bearing cup and bearing cone with the wide side facing pinion splines.

6. If equipped with double-row ball bearing: Using a 2 in. pipe or tubing, drive bearing unit into proper seating position.

7. With pinion assembly properly positioned in carrier, install new gasket. Install seal retainer onto yoke and assemble yoke and retainer assembly onto splined end of drive pinion.

8. Secure the retainer to carrier with lock washers and cap screws and torque.

9. Secure the pinion assembly with yoke washer and nut and torque to 220 ft. lbs.

DIFFERENTIAL

1. To facilitate installation of drive gear, install 2 guide pins ($\frac{1}{2} \times 20 \times 2$ in. bolts) in gear. Start the guide pins through the case flange holes and tap drive gear onto case. If a differential gear is bad, the complete set should be replaced.

2. Lubricate the differential case inner walls and all component parts with axle lubricant. Place the differential pinions and thrust washers onto the spider.

3. Assemble the side gears, pinions, side gear and pinion thrust washers onto the left half of differential.

4. Assemble the drive gear half, right half of differential, being sure to align marks on both halves.

5. Install differential-to-drive gear cap screw and lock washers and tighten evenly until drive gear is flush with case flange. Remove guide pins and install cap screws and torque.

6. Using an installer tool, install the differential side bearing cones.

7. Install the bearing cap locating dowels into the caps. Lubricate the side bearings and place the bearing cups on bearings.

8. Install the differential assembly into the carrier. Carefully install the bearing adjusters into the carrier.

9. Install the bearing caps by aligning the punch marks previously made. Be sure the bearing adjuster threads are engaged with carrier and caps. Tighten the adjusters alternately and evenly. Tighten the bearing cap screws until the lock washers are flat.

Adjustment

DRIVE GEAR AND PINION

1. Loosen the bearing cap screws, enough, to loosen the right-hand bearing adjuster (pinion side) and tighten

the left-hand bearing adjuster (opposite pinion side.) Using the adjuster, remove all backlash between the drive gear and pinion.

2. Back off the left-hand bearing adjuster about 2 notches to point where notch in adjuster is aligned with lock. Tighten the right-hand bearing adjuster solidly to seat the bearing. Loosen right-hand adjuster, enough, to free the bearing; then, retighten against the bearing. Draw up right-hand adjuster 1-2 more notches until adjuster notch aligns with the lock.

3. Using a dial indicator on carrier adjuster, slowly oscillate the drive gear and measure the backlash; it should be 0.005-0.008 in.

4. If backlash exceeds 0.008 in., loosen the right-hand adjuster 1 notch; then, tighten the left-hand adjuster 1 notch. If less than 0.005 in., loosen the left-hand adjuster 1 notch and tighten the right-hand adjuster 1 notch.

5. After the backlash has been adjusted, tighten the bearing cap screws until their respective lock washers flatten out.

6. Check the drive gear run-out.

7. Install the side bearing adjusting locknut and secure with cap screws and lock washers.

CHECKING PINION DEPTH

NOTE: This procedure is performed if the pinion is equipped with tapered roller bearings.

1. Coat the drive gear with red lead.

2. Turn the pinion shaft several revolutions in both directions while applying considerable drag on drive gear.

3. Pinion depth is determined by shim pack selection. Shim packs are available in thicknesses of: 0.012, 0.015, 0.018, 0.021 and 0.024 in.

4. Changing the pinion depth will again require adjusting backlash. After pinion depth and backlash have been adjusted, torque bearing caps.

THRUST BLOCK

1. Install the thrust block and locknut to the adjusting screw.

2. Thread the screw and block into the carrier until the block contacts the drive gear.

3. Rotate the gear and note the drag change.

4. Adjust these parts until point of greatest drag is reached. Back off the screw about a 30 degrees to provide 0.005-0.007 in. clearance between the block and gear. Make certain screw does not turn at all when torquing the locknut to 135 ft. lbs.

Exploded view of the 8 1/4 and 9 1/4 inch front differential assembly—General Motors

JEEP

Jeep models are using Dana $7\frac{9}{16}$ in. and $8\frac{7}{8}$ in. semi-floating and $8\frac{1}{2}$ in. full-floating type rear axles. The axle housings are made of a modular cast iron center section and 2 steel tubes which are pressed into the center section. The rear drum brake support plates are attached to the mounting flanges at the axle tube outboard ends.

The differential assembly consists of a cast iron case containing 2 differential side gears, 2 differential pinion gears and a pinion shaft on which the pinion gears are mounted. The differential side and pinion gears are in constant mesh.

The axle ratio and the ring and pinion gear tooth combinations are stamped on a tag attached to the differential housing cover. On the Jeep rear axles, the axle code letters are

stamped on the right side axle housing tube boss.

NOTE: The Trac-Lok limited slip differentials are available as an option. The Trac-Lok is used only in rear axles and there are 2 Trac-Lok units used.

Front Axle Assembly

DANA- $7\frac{9}{16}$ INCH AND $8\frac{7}{8}$ INCH RING GEAR AXLE

For overhaul information, refer to the Dana $7\frac{9}{16}$ in. and $8\frac{7}{8}$ in. ring gear axle, in the rear axle assembly section.

DANA- $8\frac{1}{2}$ INCH RING GEAR AXLE

For overhaul information, refer to the Dana $8\frac{1}{2}$ in. ring gear axle, in the rear axle assembly section.

Removing the pinion lock pin

Exploded view of the Dana 7⁹/₁₆ inch rear differential assembly

NOTE: When using this tool, be sure the differential case is secure. When the bearing is removed the differential case can drop if not supported.

Removing the differential bearing

2. Remove the ring gear-to-differential case bolts.

NOTE: Do not chisel or wedge the gear from the case.

Removing the pinion shaft and thrust block

3. Remove the ring gear from the case. Using a brass drift and hammer, tap the ring gear from the case; do not nick the ring gear face of the differential case or drop the gear.

4. Using a drift, remove the pinion mate shaft lockpin. Remove the pinion mate shaft and the thrust block.

Removing the axle yoke

Checking the axle housing alignment

Pinion and ring gear identifying numbers

5. Rotate the pinion gears on the side gears until the pinion gears are aligned with the case opening. Remove the pinion gears with the thrust washers and the side gears with the thrust washers.

6. Using a pinion yoke holding tool, remove the pinion nut. Using a pinion yoke removal tool, remove the axle yoke.

7. Install the axle housing cover to prevent the pinion gear from falling out when the gear is driven out of the bearings and housing. Loosely attach the cover using 2 bolts.

8. Using a seal removal tool, remove the pinion seal. Tap the end of the pinion gear with a soft face mallet to drive the pinion gear out of the front bearing. Remove the front bearing and collapsible spacer. Discard the spacer.

NOTE: The collapsible spacer is used to control the pinion bearing preload. Discard this spacer after removal, it is not reusable.

9. Remove the axle housing cover, the pinion gear and the rear bearing. Using bearing removal tools, remove the rear bearing cup.

NOTE: The pinion gear depth adjustment shims are located under the rear bearing cup; label these shims for assembly reference.

10. Using bearing removal tool, remove the front bearing cup.

NOTE: Keep the bearing cup remover tool seated squarely on the cup to prevent damaging the cup bores during removal.

Inspection

AXLE HOUSING

1. Place 2 straight-edges across the tube flanges and measure the distance between the flange ends. If the straightedges are parallel within $\frac{3}{32}$ in. at a distance of 11 inches from the tube centerline, the axle housing is serviceable.

2. Perform this inspection with the straightedges placed in horizontal and vertical positions.

DIFFERENTIAL

1. Clean each part thoroughly in solvent.

2. Towel dry the bearings or allow them to air dry, do not use compressed air to dry bearings as damage might result. Dry all other parts with compressed air or shop towels. If the parts are not to be assembled immediately, cover them to prevent dust or dirt contamination.

3. Inspect the housing for cracks and sand holes. Replace the housing if it is cracked or porous. Check for burrs and deep scratches or nicks on the gasket and oil seal surfaces. An oil stone or fine tooth file may be used to remove nicks or burrs.

4. The bearing cup bores should be carefully inspected for nicks or burrs that may have been created during bearing cup removal.

5. Inspect and clean the axle tubes. Inspect the vent to be sure it is not obstructed.

6. Check housing for bent or loose tubes or other physical damage.

7. Inspect the shaft for scoring and wear. The shaft should be a press fit of 0.000–0.010 in. in the case. Replace the shaft if worn or scored.

8. Inspect the side gears for worn, cracked or chipped teeth. The gears should fit snugly on the axle shaft splines. Also inspect the fit of the gears in the differential case bore.

9. With the gears installed, side clearance must not exceed 0.007 in. Excessive side clearance must be corrected to avoid driveline backlash resulting in a clunk noise when the transmission is initially engaged in **D** or **R** with automatic transmission.

Assembly

PINION GEAR

Ring and pinion gear sets are factory tested to detect machining variances.

Tests are started at a standard setting which is then varied to obtain the most desirable tooth contact pattern and quiet operation. When this setting is determined, the ring and pinion gear are etched with identifying numbers. The ring gear receives one number. The pinion gear receives 2 numbers which are separated by a plus (+) or a minus (–) sign.

The 2nd number on the pinion gear indicates pinion position, in relation to the centerline of the axle shafts, where tooth contact was best and gear operation was most quiet. This number represents pinion depth variance and indicates the amount in thousands of an inch the gear set varied from the standard setting.

The number on the ring gear and 1st number on the pinion gear identify the gears as a matched set; do not attempt to use a ring and pinion set having different numbers. The standard setting for Jeep axles is 2.547 in. If the pinion is marked +2, the gear set varied from standard by +0.002 in. and will require 0.002 in. less shims than a gear set marked zero (0).

When a gear set is marked plus (+), the distance from the pinion end face to the axle shaft centerline must be more than the standard setting. If the pinion gear is marked –3, the gear set varied from standard by 0.003 in. more shims than a set marked zero (0). When a set is marked minus (–), the distance from the pinion end face to the axle shaft centerline must be less than the standard setting.

NOTE: On some factory installed gear sets, an additional 0.010 or 0.020 in. may have been machined off the pinion gear bottom face. This does not affect the gear operation but does affect the pinion gear marking and depth measurement.

Pinion gears machined in this fashion have different identifying numbers. For example, if the pinion is marked +23, the number 2 indicates 0.020 in. was removed from the pinion bottom face and the number 3 indicates variance from the standard setting is +0.003 in. If the pinion is marked +16, the number 1 indicates 0.010 in. was removed from the pinion bottom face and the number 6 indicates variance from the standard setting is +0.006 in.

Gear sets with additional amounts machined off the pinion bottom face are factory installed items exclusively. All service replacement gear sets will be machined to standard settings only. In addition, replacement gear sets marked ± 0.009 in. or more or sets with mismatched identifying numbers

Old Pinion Marking	New Pinion Marking								
	- 4	- 3	- 2	- 1	0	+ 1	+ 2	+ 3	+ 4
+ 4	+ 0.008	+ 0.007	+ 0.006	+ 0.005	+ 0.004	+ 0.003	+ 0.002	+ 0.001	0

- 4	0	- 0.001	- 0.002	- 0.003	- 0.004	- 0.005	- 0.006	- 0.007	- 0.008

must be returned to the parts distributor center; do not attempt to install these gear sets.

The chart provided in this section will help to determine the approximate starter shim thickness needed for the initial pinion depth measurement. However, the chart will not provide the exact shim thickness required for final adjustment and must not be used as a substitute for an actual pinion depth measurement. The chart should be used as follows.

1. Measure the thickness of the original pinion depth shim. Note the pinion depth variance numbers marked on the old and new pinion gears.

2. Now use the chart to determine the starter shim thickness. An example of this is as follows:

If the old pinion is marked - 3 and the new pinion is marked + 2, the chart procedure would be as follows. Go to the old pinion column and locate the - 3, then go across the chart until the + 2 figure is reached in the new pinion column. The box where the 2 columns intersect will indicate the amount of starter shim thickness required.

DIFFERENTIAL

1. Install the differential bearings on the case using tools J-21784 and J-8092 or equivalent.

2. Install the thrust washers on the differential side gears and install the gears in the differential case. Install the differential pinion gears in the case. Install the thrust washers behind the pinion gears and align the pinion gear bores.

3. Rotate the differential side and pinion gears until the pinion mate

shaft bores in the pinion gears are aligned with the shaft bores in the case.

4. Install the thrust block in the case.

Insert the block through the side gear bore. Align the bore in the block with the pinion mate shaft bores in the pinion gears and case.

5. Install the pinion mate shaft. Align the lockpin bore in the shaft with the bore in the case and install the shaft lockpin.

RING GEAR

1. Position the ring gear on the differential case. Install the 2 ring gear bolts in the opposite holes and tighten the bolts to pull the gear into position.

2. Install the remaining ring gear bolts and tighten to within 105 ft. lbs. torque.

3. Position the shims previously selected to remove the differential bearing sideplay on the bearing cups and install the differential assembly in the axle housing. Install the bearing cap bolts and tighten the bolts with 85 ft. lbs. torque.

4. Attach the dial indicator to the housing. Position the indicator so the indicator stylus contacts the drive side of a ring gear tooth and at a right angle to the tooth. Move the ring gear back and forth and note the movement registered on the dial indicator. The ring gear backlash should be 0.005-0.009 in., with 0.008 in. desired.

5. Adjust the backlash as follows: to increase the backlash, install the thinner shim on the ring gear side and the thicker shim on the opposite side. To decrease the backlash, reverse the procedure; however, do not change the total thickness of the shims.

NOTE: The following is an example on how to decrease backlash. The sideplay was removed using 0.090 in. shims on each side totaling 0.180 in. Backlash is checked and found to be 0.011 in. To correct the backlash, add 0.004 in. the the shim on the ring gear side and subtract 0.004 in. from the shim on the opposite side. This will result in 0.094 in. shim on the ring gear side and 0.086 in. shim on the other side. The backlash will be approximately 0.007-0.008 in. The total shim thickness remains 0.180 in.

Adjustment

PINION DEPTH MEASUREMENT

1. Measure the thickness of the original pinion depth shim. Note the pinion depth variance numbers marked on the old and new pinion gears.

2. Determine the starter shim thickness. Using the chart, determine the amount to be added or subtracted

Measuring the ring gear backlash

25 DRIVE AXLES DOMESTIC

from the original shim thickness for starter shim thickness.

NOTE: The starter shim thickness must not be used as a final shim setting. An actual pinion depth measurement must be performed and the final shim thickness adjusted, as necessary.

3. Install the ring bearing on the pinion gear with the large diameter of the bearing cage facing the gear end of the pinion. Press the bearing against the rear face of the gear.

4. Clean the pinion bearing bores in the axle housing thoroughly. This is important in obtaining the correct pinion gear depth adjustment. Install the starter pinion depth shim in the housing rear bearing cup bore. Be sure the shim is centered in the bearing cup bore.

NOTE: If the shim is chamfered, be sure the chamfered side faces the bottom of the bearing cup bore.

5. Install the ring bearing cup using tools J-8092 and J-8608 or equivalent. Install the front bearing cup using tools J-8092 and J-8611-01 or equivalent. Install the pinion gear in the rear bearing cup.

6. Install the front bearing, rear universal joint yoke and original pinion nut on the pinion gear. Tighten the pinion nut only enough to remove the bearing endplay.

Installing the gauge arbor tool, discs and the gauge block tool

Measuring the anvil with a micrometer

NOTE: Do not install a replacement pinion nut and collapsible spacer at this time as the pinion gear will be removed after depth measurement.

7. Note the pinion depth variance marked on the pinion gear. If the number is preceded by a plus (+) sign, add that amount (in thousandths) to the standard setting for the axle model being overhauled. If the number is preceded by a minus (-) sign, subtract that amount (in thousandths) from the standard setting. The result of this addition or subtraction is the desired pinion depth. Record this figure for future reference.

8. Assemble an arbor tool J-5223-4 and discs J-5223-23 or equivalent, install the assembled tools in the differential bearing cup bores; be sure the discs are completely seated in bearing cup bores.

9. Install the bearing caps over the discs and install the bearing cap bolts. Tighten the bearing cap bolts securely but not with the specified torque.

10. Position a gauge block tool J-5223-20 or equivalent, on the end face of the pinion gear with the anvil end of the gauge block seated on the gear and the gauge plunger under the arbor tool J-5223-4 or equivalent.

11. Assemble and mount the clamp tool J-5223-24 and bolt J-5223-29 or equivalent, on the axle housing. Use the axle housing cover bolt to attach the clamp to the housing.

12. Extend the clamp bolt until it presses against the gauge block with enough force to prevent the gauge block from moving. Loosen the gauge block thumb screw to release the gauge block plunger. When the plunger contacts the arbor tool, tighten the thumbscrew to lock the plunger in position; do not disturb the plunger position.

13. Remove the clamp and bolt assembly from the axle housing. Remove the gauge block and measure the distance from the end of the anvil to the end of the plunger using a 2-3 in. micrometer. This dimension represents the measured pinion depth. Record this dimension for assembly reference.

14. Remove the bearing caps, the arbor tool and discs from the axle housing. Remove the pinion gear, the rear bearing cup and pinion depth shim from the axle housing.

15. Measure the thickness or the depth shim. Add this dimension to the measured pinion depth. From this total, subtract the desired pinion depth. The result represents the correct shim thickness required.

NOTE: The desired pinion depth is the standard setting plus

or minus the pinion depth variance.

PINION GEAR BEARING PRELOAD

1. Install the correct thickness pinion depth shim(s) in the axle housing bearing cup bore. Install the rear bearing cup and pinion gear.

NOTE: The collapsible spacer controls the pinion bearing preload; do not reuse the old spacer, use a replacement spacer only.

2. Install the replacement collapsible spacer and front bearing on the pinion gear. Install the pinion oil seal using tool J-22661 or equivalent.

3. Install the pinion yoke, replace the pinion nut and tighten the pinion nut finger-tight. Tighten the pinion nut enough to remove endplay and seat the pinion bearings. Using tool J-22575 or equivalent, tighten the nut and use tool J-86141-01 or equivalent, to hold the yoke while tightening the nut.

4. Rotate the pinion, while tightening the nut, to seat the bearings evenly. Remove the tools.

NOTE: Do not exceed the specified preload torque or loosen the nut to reduce the preload torque, if the specified torque is exceeded.

5. Using an inch lb. torque wrench and adapter tool J-22575 or equivalent, measure the torque required to turn the pinion gear; the correct pinion bearing preload torque is 17-25 inch lbs. Continue tightening the pinion nut until the required preload torque is obtained.

6. If the pinion bearing preload torque is exceeded, remove the pinion gear, replace the collapsible spacer and pinion nut and adjust the preload again.

DIFFERENTIAL BEARING

1. Place the bearing cup over each differential bearing and install the dif-

Installing the shim(s) on the side of the differential bearing cup

ferential case assembly in the axle housing.

2. Install the shim on each side between the bearing cup and the housing; use 0.080 in. shims as the starting point.

3. Install the bearing caps and tighten the bolts finger-tight. Mount the dial indicator on the housing. Using a prybar, pry between the shims and housing. Pry the assembly to one side and zero the indicator, then, pry the assembly to the opposite side and read the indicator.

NOTE: Do not zero or read the indicator while prying.

4. The amount read on the indicator is the shim thickness that should be added to arrive at the zero preload and zero endplay. Repeat the procedure to ensure accuracy and adjust if necessary; shims are available in thicknesses from 0.080–0.110 in. in increments of 0.002 in.

5. When the sideplay is eliminated, a slight bearing drag will be noticed. Install the bearing caps and tighten the bearing cap bolts to with 85 ft. lbs. torque.

6. Attach the dial indicator to the axle housing and check the ring gear mounting face of the differential case for runout; runout should not exceed 0.002 in.

7. Remove the case from the housing. Retain the shims used to adjust the sideplay.

DIFFERENTIAL AND BEARING PRELOAD

NOTE: The differential bearings must be preloaded to compensate for heat and loads during operation. The differential bearings are preloaded by increasing the shim pack thickness at each side of the differential by 0.004 in. for a total of 0.008 in.

1. Remove the differential assembly from the housing. Be sure to keep the differential bearing shim packs together for the proper assembly. Do not distort the shims in the axle housing bearing bores.

2. Install the differential bearing cups on the differential bearings. The cups should cover the differential bearing rollers completely. Position the differential assembly in the housing so the bearings just start into the housing bearing bores.

NOTE: Slightly tipping the bearing cups will ease starting them into the bores. Also keep the differential assembly square in the housing during installation and push it in as far as possible.

Installation of the dial indicator

3. Tap the outer edge of the bearing cups until the differential is seated in the housing.

4. Install the differential bearing caps. Position the caps accordingly to the alignment punch marks made at disassembly. Tighten the bearing cap bolts with 85 ft. lbs. torque. Preloading the differential bearings may change the backlash setting. Check and correct the backlash, if necessary.

5. Install the propeller shaft, aligning the index marks made at disassembly. Install the axle shafts, bearings, seals and brake support plates. Fill the rear axle with the specified axle lubricant.

6. Check and adjust the axle shaft endplay, if necessary. Adjust the endplay at the left side of the axle shaft only. Install the hubs, drums and wheels.

Lower the vehicle and road test the vehicle to check the rear axle assembly for proper operation.

DANA—8½ INCH RING GEAR AXLE

Disassembly

DIFFERENTIAL

1. Remove the housing cover and drain the lubricant.

2. Using an axle spreader tool, mount it onto the axle housing and spread the housing enough to remove the differential.

3. Using a dial indicator, measure the amount the opening is being spread; do not spread the housing more than 0.015 in. (0.38mm), for damage to the housing may occur.

4. Mark the differential bearing caps for reassembly purposes.

5. Loosen the bearing caps until 2–3 threads are engaged.

6. Using a prybar, pry the differential loose.

7. Remove the bearing caps and the differential.

8. Mount the differential into a vise.

9. Remove and discard the ring gear bolts; they are not reusable.

10. Using a brass drift and a hammer, tap the ring gear from the differential.

11. Using a differential bearing puller, press the differential bearings from the differential.

12. Remove the differential bearing shims.

13. Using 2 sets of feeler gauges, insert them between each side of the side gear thrust washer and differential case and measure the side gear clearance; the clearance should not exceed 0.007 in. (0.18mm). Replace both thrust washers, if the clearance exceeds the tolerance.

14. Remove the pinion shaft lockpin and pinion shaft.

15. Rotate the pinions to remove them through the case opening.

16. Remove the side gears and thrust washers.

PINION GEAR

1. Remove the differential case from the axle housing.

2. Using a pinion yoke holding tool, remove the pinion gear nut.

Measuring the side gear clearance

Spreading the axle housing

25 DRIVE AXLES DOMESTIC

Exploded view of the Dana 8½ inch rear differential assembly

3. Using a pinion yoke holder tool and a pinion puller tool, press the yoke from the pinion gear. Remove the pinion washer.

4. Using a soft mallet, drive the pinion gear from the axle housing.

5. Remove the pinion gear, the bearings and the preload spacers.

6. Remove and discard the pinion seal.

7. Using a shop press and the bearing removal tool, press the bearing from the pinion gear.

Inspection

1. Clean the differential components in solvent and use compressed air to dry them; do not use compressed air on the bearings, only shop towels.

2. Check the components for wear or damage; replace them, if necessary.

3. Inspect the bearings and bearing cups for wear, cracks or scoring; replace them, if necessary.

4. Inspect the differential side and pinion gears for wear, cracks or chips; replace them, if necessary.

5. Inspect the ring and pinion gears for wear and/or damage; replace them, if necessary.

6. Inspect the differential case for cracks or damage; replace it, if necessary.

Assembly

PINION GEAR

1. Make sure the ring and pinion are a matched set.

2. Measure the thickness of the

OLD PINION MARKING	NEW PINION MARKING								
	-4	-3	-2	-1	+0	+1	+2	+3	+4
+4	+0.008	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0
+3	+0.007	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	-0.001
+2	+0.006	+0.005	+0.004	+0.003	+0.002	+0.001	0	-0.001	-0.002
+1	+0.005	+0.004	+0.003	+0.002	+0.001	0	-0.001	-0.002	-0.003
0	+0.004	+0.003	+0.002	+0.001	0	-0.001	-0.002	-0.003	-0.004
-1	+0.003	+0.002	+0.001	0	-0.001	-0.002	-0.003	-0.004	-0.005
-2	+0.002	+0.001	0	-0.001	-0.002	-0.003	-0.004	-0.005	-0.006
-3	+0.001	0	-0.001	-0.002	-0.003	-0.004	-0.005	-0.006	-0.007
-4	0	-0.001	-0.002	-0.003	-0.004	-0.005	-0.006	-0.007	-0.008

original pinion shim and note the variance on the pinion gear.

3. Perform the following procedure to determine the pinion starter shim thickness:

a. If the original ring and pinion are being installed, use the original shim.

b. If a replacement gear set is being installed, determine the best starter shim thickness.

c. Refer to the pinion variance chart and observe where the old and new pinion marking column intersect.

d. If the old pinion is +1 and the new pinion is -3, the intersecting figure is +0.004 in. (0.10mm); add this amount to the original shim. Or, if the old pinion is -3 and the new pinion is -2, the intersecting figure is -0.001 in. (-0.025mm); subtract this amount from the original shim.

4. Install the starter shim in the pinion rear bearing cup bore; if the shim is chamfer on one side, position the chamfered side so it faces the bottom of the bore.

5. Using a driver tool, install the pinion rear bearing cup into the axle housing.

6. Install the front bearing cup.

7. Using a shop press, press the rear bearing onto the pinion gear.

8. Install the pinion gear into the axle housing and the front bearing onto the pinion; do not install the slinger or the seal.

9. Install the yoke, the pinion nut washer and the old pinion nut; tighten the nut enough to remove the endplay.

10. Adjust the backlash and gear tooth contact.

DIFFERENTIAL

1. Install the side gears, the thrust washers and the pinion gears into the differential case.

NOTE: Be sure to install new side gear thrust washers, if the clearance measured at disassembly exceeded 0.007 in. (0.18mm).

2. Using 2 sets of feeler gauges, insert them between each side of the side gear thrust washer and differential case and measure the side gear clearance; the clearance should not exceed 0.007 in. (0.18mm). Replace both thrust washers, if the clearance exceeds the tolerance.

3. Install the pinion shaft and lockpin into the case.

4. Assemble the original differential bearing shim packs, then, remove approximately 0.20 in. (0.50mm) shim thickness from each pack; the remaining shims will serve as a starter shim pack.

View of the gear tooth nomenclature

5. Install the starter shim packs and bearing onto the case.

6. Align and install the ring gear. Using new bolts, torque the ring gear-to-differential case bolts to 55 ft. lbs. (75 Nm).

7. Install the spreader tool onto the axle housing. Using a dial indicator, spread the axle housing no more than 0.015 in. (0.38mm).

NOTE: Do not spread the housing more than 0.015 in. (0.038mm), for damage may occur to the case.

8. Install the differential; it may be necessary to tap the differential bearing cups, with a soft hammer, to seat them.

9. Install the differential bearing caps and torque the bolts to 57 ft. lbs. (77 Nm).

10. Remove the spreader tool and dial indicator.

11. Adjust the ring and pinion gear.

12. Using silicone sealant, apply a bead of it to the axle housing. Install the cover and torque the bolts to 35 ft. lbs. (47 Nm).

Adjustment

RING AND PINION

1. Using yellow ferrous oxide compound, coat the drive and coast sides of the ring gear teeth.

2. Install the differential and tighten the bearing caps.

3. Using a dial indicator, mount it onto the housing, position the stylus against the drive side of one ring gear tooth; be sure the stylus is at a right angle to the tooth.

4. Move the ring gear toward the dial indicator and zero it.

5. Move the ring gear away from the pinion until the backlash is 0.005-0.009 in. (0.13-0.23mm). Insert shims or feeler gauges between the differential bearings and housing to maintain the backlash during the remainder of the adjustment.

NOTE: To increase the backlash, subtract shims from the ring gear side of the case. To decrease

the backlash, add shims to the ring gear side of the case.

6. Move the dial indicator aside and recoat any necessary ring gear teeth with the ferrous oxide compound.

7. Rotate the ring gear a complete revolution in both directions and note the tooth contact pattern imprinted in the compound.

8. Adjustments can be made as follows:

a. Decreasing the backlash moves the drive and coast side pattern slightly lower and toward the toe.

b. Increasing the backlash move the drive and coast side pattern slightly higher and toward the heel.

c. A thicker pinion shim moves the pinion closer to the ring gear. The drive pattern moves deeper on the tooth and slightly towards the heel.

d. A thinner pinion shim moves the pinion away from the ring gear. Drive pattern moves toward the top of the tooth and toward the heel. Coast pattern moves toward the top of the tooth and slightly toward the toe.

9. Remove the differential and pinion gear.

10. Change the pinion and differential shims, as necessary.

11. Install the pinion and differential.

12. Recheck the tooth contact pattern and backlash; adjust, as necessary.

PINION BEARING PRELOAD

1. Using a yoke holding tool, torque the pinion nut to a minimum of 210 ft. lbs. (285 Nm).

2. Using an inch lb. torque wrench, measure the torque necessary to rotate the pinion; the torque should be 20-40 inch lbs. (2-5 Nm).

NOTE: If the torque is not correct, add shims to increase the preload or subtract shims to decrease the preload.

3. Remove the pinion nut, the washer and the yoke after setting the preload; be sure to discard the old nut.

4. Lubricate the new pinion oil seal lip and install the seal into the axle housing.

5. Install the yoke, the washer and a new pinion nut; torque the nut to a minimum of 210 ft. lbs. (285 Nm).

DIFFERENTIAL BEARING PRELOAD

1. Remove the differential bearing from the side of the case opposite the ring gear.

2. Add a 0.015 in (0.38mm) shim the shim pack on the side of the case.

3. Reinstall the bearing onto the case.

25 DRIVE AXLES DOMESTIC

4. Clean the ferrous oxide compound from the ring and pinion gears, then, lubricate the differential gears and bearings with axle lubricant.

5. Install the spreader tool onto the axle housing. Using a dial indicator, spread the axle housing no more than 0.015 in. (0.38mm).

NOTE: Do not spread the housing more than 0.15 in. (0.38mm), for damage may occur to the case.

6. Install the differential; it may be necessary to tap the differential bearing cups, with a soft hammer, to seat them.

7. Install the differential bearing caps and torque the bolts to 57 ft. lbs. (77 Nm).

8. Recheck the backlash; it should be 0.005–0.009 in. (0.13–0.23mm). If necessary, reset the backlash.

TRAC-LOK DIFFERENTIAL

Operational Test

If a noisy or rough operation such as a chatter occurs when turning corners, the most probable cause of this chatter or noise is incorrect or contaminated lubricant. Before removing the Trac-Lok unit for repair, drain, flush and refill the axle with the specified lubricant. A complete lubricant drain and refill with the specified fluid will usually correct the chatter problem. A quick operational test of the Trac-Lok differential can be done easily by performing the following steps.

Removing the snapring from the pinion mate shaft

Install the step plate tool

Install the gear rotating tool

1. Position one wheel on solid dry pavement and the opposite wheel on ice, mud grease or a similar low traction surface.

2. Gradually, increase the engine rpm to obtain the maximum traction prior to a breakaway. The ability to move the vehicle effectively will demonstrate the proper performance.

NOTE: If the test is performed on extremely slick surfaces such as ice or grease coated surfaces, some question may exist as to proper performance. In these extreme cases, a properly performing Trac-Lok will provide greater pulling power by lightly applying the parking brake.

Disassembly

DIFFERENTIAL

1. Remove the differential from the axle housing as previously outlined in this section. Install one axle shaft in the vise with the spline end facing upward and tighten the vise.

2. Do not allow more than 2 3/4 in. of the shaft to extend above the top of the vise. This prevents the shaft from fully entering the side gear, causing interference with the step plate tool used to remove the differential gears.

3. Mount the differential case on the axle shaft with the ring gear bolt heads facing upward. Place some shop towels under the ring gear to protect the gear when it is removed from the case.

4. Remove and discard the ring gear bolts. Remove the ring gear from the

1. Thrust block
2. Snapring
3. Pinion gear
4. Thrust washer
5. Pinion shaft
6. Retainer clip
7. Clutch pack
8. Belleville spring
9. Side gear
10. Case
11. Ring gear

Exploded view of the Trac-Loc differential

case, using a rawhide hammer. Remove the differential case from the axle shaft and remove the ring gear and remount the differential case on the axle shaft.

5. Use suitable tools to disengage the snaprings from the pinion mate shaft. Place a shop towel on the opposite opening of the case to prevent the snaprings from flying out of the case. Remove the pinion mate shaft using a hammer and brass drift.

NOTE: A special gear rotating tool J-23781-3 or equivalent, is required to perform the following steps. The tool consists of 3 parts; the gear rotating tool, forcing screw and step plate.

6. Install step plate tool into the lower differential side gear. Position the pawl end of the gear rotating tool onto the step plate.

7. Insert the forcing screw tool through the top of the case and thread it into the gear rotating tool. Before using the forcing screw tool, apply a small amount of grease to the centering hole in the step plate and oil the threads of the forcing screw.

8. Center the forcing screw in the step plate and tighten the screw to move the differential side gears away from the differential pinion gears. Remove the differential pinion gear thrust washers using a feeler gauge or a shim stock of 0.030 in. thickness. Insert the feeler gauge or shim stock between the washer and the case and withdraw the shim stock with the thrust washer.

9. Tighten the forcing screw until a slight movement of the differential pinion gear is observed. Insert the pawl end of the gear rotating tool between the teeth of one differential side gear.

10. Pull the handle of the tool to rotate the side gears and pinion gears. Remove the pinion gears as they appear in the case opening. It could be necessary to adjust the tension applied on the belleville springs by the forcing screw before the gears can be rotated in the case.

Removing the pinion gear thrust washers

11. Retain the upper side gear and clutch pack in the case by placing a hand on the bottom of the rotating tool while removing the forcing screw. Remove the rotating tool, upper side gear and clutch pack.

12. Remove the differential case from the axle shaft. Invert the case with the flange or ring gear side up and remove the step plate tool, lower the side gear and clutch pack from the case. Remove the retainer clips from both the clutch packs to allow separation of the plates and discs.

Inspection

If any member of either clutch pack shows evidence of excessive wear or scoring, the complete clutch pack must be replaced on both sides.

1. Thoroughly, clean each part in solvent.

2. Towel dry bearings or allow them to air dry, do not use compressed air to dry bearings as damage might result. Dry all other parts with compressed air or shop towels. If the parts are not to be assembled immediately, cover them to prevent dust or dirt contamination.

3. Inspect the housing for cracks and sand holes. Replace the housing if it is cracked or porous. Check for burrs and deep scratches or nicks on the gasket and oil seal surfaces. An oil stone or fine tooth file may be used to remove nicks or burrs.

4. Inspect the bearing cup bores for nicks or burrs that may have been created during bearing cup removal.

5. Inspect and clean the axle tubes. Inspect the vent to be sure it is not obstructed.

6. Check housing for bent or loose tubes or other physical damage.

7. Inspect the side gears for worn, cracked or chipped teeth. The gears should fit snugly on the axle shaft splines. Also, inspect the fit of the gears in the differential case bore.

Assembly

DIFFERENTIAL

1. Lubricate all the differential components with the specified gear lubricant. Assemble the clutch packs. Install the plates and discs in the same position as when removed regardless of whether they are replacement or original parts.

2. Install the clutch retainer clips on the ears of the clutch plates. Be sure the clutch packs are completely assembled and seated on the ears of the plates. Install the clutch packs on the differential side gears and install the assembly in the case.

3. Make sure the clutch pack stays assembled on the side gear splines and

Installing the clutch packs

the retainer clips are completely seated in the case pockets. To prevent the pack from falling out of the case, it will be necessary to hold it in place by hand while mounting the case on the axle shaft.

NOTE: When installing the differential case on the axle shaft, make sure the splines of the side gears are aligned with those of the axle shaft. Make sure the clutch pack is still properly assembled in the case after installing the case on the axle shaft.

4. Mount the case assembly on the axle shaft. Install the step plate tool in the side gear and apply a small amount of grease in the centering hole of the step plate.

Keeping the side gear rotating tool in position

Installing the forcing screw into the rotating tool

Installing the thrust washers

5. Install the remaining clutch pack and side gear. Make sure the clutch pack stays assembled on the side gear splines and the retainer clips are completely seated in the pockets of the case.

6. Position the gear rotating tool in the upper side of the gear. Keep the side gear and rotating tool in position by holding them with your hand. Insert the forcing screw through the top of the case and thread it into the rotating tool.

7. Install both of the differential pinion gears in the case; be sure the bores of the gears are aligned. Hold the gears in place by hand. Tighten the forcing screw to compress the belleville springs and provide clearance between the teeth of the pinion gears and the side gears.

8. Position the pinion gears in the case and insert the rotating tool pawl between the side gear teeth. Rotate the side gears by pulling on the tool handle and install the pinion gears.

NOTE: If the side gears will not rotate, the belleville spring load

Universal Joint Strap Bolts	19 N·m (170 in-lbs)	16-22 N·m (140-200 in-lbs)

Torque specifications for the Trac-Lock differential

will have to be adjusted. If adjustment is necessary, loosen or tighten the forcing screw slightly until the gears will rotate.

9. Rotate the side gears, using the rotating tool handle, until the shaft bores in both the pinion gears are aligned with the case bore. Lubricate both sides of the pinion gear thrust washers.

10. Tighten or loosen the forcing screw to permit the thrust washer installation. Install the thrust washers and using a suitable tool, guide the washers into position. Make sure the shaft bores in the washers and gears are aligned with the case bores.

11. Remove the forcing screw, rotat-

ing tool and step plate. Lubricate the pinion mate shaft and seat the shaft in the case. Be sure the snapping grooves in the shaft are exposed to allow the snapping installation.

12. Install the pinion mate shaft snaprings, remove the case from the axle shaft and install the ring gear on the case. Be sure to use replacement ring bolts only; do not reuse the original bolts.

13. Align the ring gear and case bolt holes and install the ring gear bolts finger tight only. Remove the case on the axle shaft and tighten the bolts evenly to the proper torque specifications.

14. Install the differential assembly into the axle housing.

IMPORT DRIVE AXLES

General Information

DIFFERENTIAL OPERATION

The differential is an arrangement of gears that permits the wheels to turn at different speeds when cornering and divides the torque between the axle shafts. The differential gears are mounted on a pinion shaft and the gears are free to rotate on this shaft. The pinion shaft is fitted in a bore in the differential case and is at right angles to the axle shafts.

Power flow through the differential is as follows. The drive pinion, which is turned by the driveshaft, turns the ring gear. The ring gear, which is bolted to the differential case, rotates the case. The differential pinion forces the pinion gears against the side gears. In cases where both wheels have equal traction, the pinion gears do not rotate on the pinion shaft, because the input force of the pinion gear is divided equally between the 2 side gears. Consequently the pinion gears revolve with the pinion shaft, although they do not revolve on the pinion shaft itself. The side gears, which are splined to the axle shafts and meshed with the pinion gears, rotate the axle shafts.

GEAR RATIOS

The drive axle of a vehicle is said to have a certain axle ratio. This number (usually a whole number and a decimal fraction) is actually a comparison of the number of gear teeth on the ring gear and the pinion gear. For example, a 4:11 rear means that theoretically, there are 4:11 teeth on the ring gear and one tooth on the pinion. Actually, on a 4:11 rear, there are 37 teeth on the ring gear and nine teeth on the pinion gear. By dividing the number of teeth on the pinion gear into the number of teeth on the ring gear, the numerical axle ratio (4:11) is obtained.

Differential Diagnosis

The most essential part of rear axle service is proper diagnosis of the problem. Any gear driven unit will produce a certain amount of noise. Acceptable or normal noise can be classified as a slight noise heard only at certain speeds or under unusual conditions. This noise tends to reach a peak at 40-60 mph depending on the road condition, load, gear ratio and tire size.

Frequently, other noises are mistakenly diagnosed as coming from the axle assembly. Vehicle noises from tires, transmission, driveshaft, U-joints and front and rear wheel bearings will often be mistaken as emanating from the front or rear axle assemblies.

EXTERNAL NOISE ELIMINATION

It is advisable to make a thorough road test to determine whether the noise originates in the axle assembly or whether it originates from the tires, engine transmission, wheel bearings or road surface. Noise originating from other places cannot be corrected by overhauling the axle assemblies.

ROAD NOISE

Brick roads or rough surfaced concrete, may cause a noise which can be mistaken as coming from the axle assembly. Driving on a different type of road (smooth asphalt or dirt) will determine whether the road is the cause of the noise. Road noise is usually the same on drive or coast conditions.

TIRE NOISE

Tire noise can be mistaken as axle assembly noises, even though the tires are at fault. Snow tread and mud tread tires or tires worn unevenly will frequently cause vibrations which seem to originate elsewhere; temporarily and for test purposes only, inflate the tires to 40-50 lbs. This will significantly alter the noise produced by the tires, but will not alter noise from the axle assembly. Noises from the axle assembly will normally cease at speeds below 30 mph on coast, while tire noise will continue at lower tone as vehicle speed is decreased. The axle noise will usually change from drive conditions to coast conditions, while tire noise will not. Do not forget to lower the tire pressure to normal after the test is complete.

ENGINE AND TRANSMISSION NOISE

Engine and transmission noises also seem to originate in the axle assemblies. Road test the vehicle and determine at which speeds the noise is most pronounced. Stop the vehicle in a quiet place to avoid interfering noises. With the transmission in N position, run the engine slowly through the engine speeds corresponding to the vehicle speed at which the noise was most noticeable. If a similar noise was produced with the vehicle standing still,

the noise is not in the axle assemblies, but somewhere in the engine or transmission.

FRONT WHEEL BEARING NOISE

Front wheel bearing noises, sometimes confused with axle noises, will not change when comparing drive and coast conditions. While holding the vehicle speed steady, lightly apply the footbrake. This will often cause wheel bearing noise to lessen, as some of the weight is taken off the bearing. Front wheel bearings are easily checked by jacking up the wheels and spinning the wheels. Shaking the wheels will also determine if the wheel bearings are excessively loose.

AXLE ASSEMBLY NOISE

If a logical test of the vehicle shows that the noise is not caused by external items, it can be assumed that the noise originates from the axle assembly. The axle assembly should be tested on a smooth level road to avoid road noise. It is not advisable to test the axle by jacking up the wheels and running the vehicle.

True axle noises generally fall into 2 classes; gear noise and bearing noises and can be caused by a faulty driveshaft, faulty wheel bearings, worn differential or pinion shaft bearings, U-joint misalignment, worn differential side gears and pinions, or mismatched, improperly adjusted, or scored ring and pinion gears.

REAR WHEEL BEARING NOISE

A rough rear wheel bearing causes a vibration or growl which will continue with the vehicle coasting or in neutral. A brinelled rear wheel bearing will also cause a knock or click noise. Jack up the rear wheels and spin the wheel slowly, listening for signs of a rough or brinelled wheel bearing.

DIFFERENTIAL SIDE GEAR AND PINION NOISE

Differential side gears and pinions seldom cause noise since their movement is relatively slight on straight ahead driving. Noise produced by these gears will be more noticeable on turns.

PINION BEARING NOISE

Pinion bearing failures can be distinguished by their speed of rotation, which is higher than side bearings or

axle bearings. Rough or brinelled pinion bearings cause a continuous low pitch whirring or scraping noise beginning at low speeds.

SIDE BEARING NOISE

Side bearings produce a constant rough noise, which is slower than the pinion bearing noise.

Bearing Diagnosis

This section will help in the diagnosis of bearing failure and the causes. Bearing diagnosis can be very helpful in determining the cause of axle assembly failure.

When disassembling a axle assembly, the general condition of all bearings should be noted and classified where possible. Proper recognition of the cause will help in correcting the problem and avoiding a repetition of the failure. Some of the common causes of bearing failure are:

1. Abuse during assembly or disassembly.
2. Improper assembly methods.
3. Improper or inadequate lubrication.
4. Bearing contact with dirt or water.
5. Wear caused by dirt or metal chips.
6. Corrosion or rust.
7. Seizing due to overloading.
8. Overheating.
9. Fretting of the bearing seats.
10. Brinelling from impact or shock loading.
11. Manufacturing defects.
12. Pitting due to fatigue.

To avoid damage to the bearing from improper handling, it is best to treat a used bearing the same as a new bearing. Always work in a clean area with clean tools. Remove all outside dirt from the housing before exposing a bearing and clean all bearing seats before installing a bearing. Never spin a bearing, either by hand or with compressed air.

General Service and Inspection

CLEANING BEARINGS

Proper bearing cleaning is important. Bearings should always be cleaned separately from other rear axle parts.

1. Soak all bearings in clean kerosene or diesel fuel oil. Ordinary gasoline should not be used. Bearings should not be cleaned in hot solution tank.

2. Slush bearings in cleaning solution until all oil lubricant is loosened.

Brush bearings with soft bristled brush until all dirt has been removed. Remove loose particles of dirt by striking flat against a wood block.

3. Rinse bearings in clean fluid. While holding races to prevent rotation, blow dry with compressed air. Do not spin bearings while drying.

4. After bearings have been inspected, lubricate thoroughly with regular axle lubricant; then wrap each bearing in clean cloth until ready to use.

CLEANING PARTS

Immerse all parts in suitable cleaning fluid and clean thoroughly. Use a stiff bristle brush as required to remove foreign deposits. Clean all lubricant passages or channels in pinion cage, carrier, caps and retainers. Make certain that interior of housing is thoroughly cleaned. Clean vent plugs and breathers. Small parts such as cap screws, bolts, studs, nuts etc., should be cleaned thoroughly.

INSPECTION

Magna Flux or equivalent test all steel parts, except ball and roller bearings, to detect presence of wear and cracks.

BEARINGS

Rotate each bearing and check to see if the rollers are worn, chipped, rough or in any other way damaged. Check the cage to see if it is in any way damaged. If either the bearing rollers or the cage are damaged the bearing must be replaced.

GEARS

Examine drive gear and drive pinion, differential pinions and differential side gears carefully, for damaged teeth, worn spots in surface hardening, distortion and where drive gear is attached to differential case with rivets, inspect rivets for looseness, replace loose rivets. Check radial clearances between differential side gears and differential case. Check fit of differential pinions on spider.

DIFFERENTIAL CASE

Inspect case for cracks, distortion or damage, if in good condition, thoroughly clean case and cover; then assemble case with bolts and mount in lathe centers of block stand. If lathe is not available, install differential side bearings and mount case in differential carrier. Install dial indicator and check differential case run out.

Differential case with drive gear installed is checked in the same manner, except that dial indicator reading must be taken at gear instead of at case flange.

AXLE SHAFTS

Examine splined end of axle shaft for twisted or cracked splines, twisted shaft and worn dowel holes in flange. Install new shafts if necessary.

Install axle shaft assembly in lathe centers and check shaft run out with dial indicator so that indicator shaft end contacts inner surface of flange near outer edge of flange and check flange run out.

SHIMS

Carefully inspect shims for uniform thickness. Where various thickness of shims are used in a pack, it is recommended that the thickest shims be used between the thin shims.

THRUST WASHERS

Replace all thrust washers upon installation.

SPIDER ASSEMBLY

Carefully inspect spider components for wear or defects.

PINION BUSHINGS

Examine bushings (when used) for excessive wear, looseness, or damage. Check fit of gears on spider for excessive clearance.

AXLE HOUSING SLEEVES

Sleeves showing damaged threads, wear, or other damage should be replaced as necessary.

CHRYSLER IMPORT/ MITSUBISHI

Front Drive Axle

Inspection Before Dissassembly

1. Position the removed differential carrier assembly in a suitable holding fixture. Remove the differential cover.

2. With the drive pinion locked in place, measure the final drive gear

(ring gear) backlash with a dial indicator on the drive gear. Measure at 4 points or more on the drive gear. If the backlash is not within the standard valve, adjust it by using the correct side bearing spacer.

3. The final drive gear backlash standard valve is 0.0043–0.0063 in. on all engines.

4. Measure the drive gear runout at the shoulder on the reverse side of the drive gear the limit is 0.0020 in. on all engines.

5. While locking the side gear with a wedge or equivalent, measure the differential gear backlash with a dial indicator on the pinion gear. The standard valve is 0–0.0030 in. The service limit is 0.008 in. on all engines.

6. Check the final drive gear tooth contact by the following steps:

a. Apply a thin uniform coat of machine blue or equivalent to both surfaces of the drive gear teeth.

b. Insert a tool between the differential carrier and the differential case and then rotate the companion flange by hand (once in normal direction and once reverse direction) while applying a load to the drive gear so that the revolution torque (about 2.5 ft. lbs.) is applied to the drive pinion.

c. If the drive gear is rotated too much, contact pattern will become unclear and difficult to read. If a correct pattern cannot be obtained (drive gear and pinion

worn beyond allowable limits), replace the drive gear and the drive pinion as a set.

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture. Remove the differential cover.

2. Matchmark and remove the bearing (carrier) caps and pry out the differential assembly.

3. Remove the differential side bearings. Be sure to keep the right and left bearings and shims separated. Remove side bearings inner and outer races.

4. Matchmark ring gear assembly and loosen the ring gear mounting

STEP 1

STEP 3

STEP 2

STEP 4

Adjustment of pinion height—front differential carrier

bolts in diagonal sequence. Remove the ring gear.

5. Drive the pinion shaft lock pin out from the rear of the ring gear using a punch and remove the pinion shaft assembly.

STEP 1

STEP 2

Adjustment of drive pinion preload—front differential carrier

6. Remove the pinion gears and washers. Remove the side gears with their spacers. Keep left and right side gears and spacers separate. Remove the differential case.

7. Hold the end yoke (companion flange) and remove the self-locking nut and washer. Matchmark for correct installation then remove the companion flange.

8. Tap the end of the drive pinion shaft (matchmark shaft assembly for correct installation) with a plastic hammer and force out the drive pinion along with its adjusting shim, the rear inner race, the drive pinion spacer and the preload adjusting shim. The rear bearing inner race can be pressed off the pinion shaft.

9. Remove the front and rear pinion bearing outer races. Remove the oil seals. Remove the vent plug if necessary and gear carrier case.

10. Install the vent plug to the gear carrier case if necessary. Install oil seals.

11. Press the drive pinion front and rear bearing outer races into the differential carrier case. Make sure that the races do not tilt and that they sit fully in the case.

12. At this point of the reassembly, adjust the drive pinion height by following this procedure:

a. Install special service tool C-4626 and drive pinion front and rear

bearing inner races to the gear carrier in the correct sequence.

b. Gradually tighten the nut of the special tool until the standard valve of the drive pinion turning torque is reached.

c. Measure the drive pinion turning torque without the oil seal installed. The standard valve is 1.30–2.17 inch lbs. of turning torque for all engines except 3.0L engine. The standard valve is 3.47–4.34 inch lbs. of turning torque for 3.0L engine.

d. Because one rotation cannot be made when the special tool is in contact with the gear carrier, move it a few times and after seating the bearing measure the rotation torque.

STEP 1

STEP 2

STEP 3

Adjustment of differential gear backlash—front differential carrier

e. Mount the special service tool MB990552 in the side bearing seat of the gear carrier and then select a drive pinion front height adjusting shim (keep front shims to a minimum) of a thickness which corresponds to the gap between the special tools. Be sure to clean the side bearing seat thoroughly. When mounting the special tool be sure that the cut-out sections are in the correct position and also confirm that the tool is in close contact with the side bearing seat.

f. Install the selected drive pinion front shim(s) to the drive pinion. Using special tool MB990802, press fit the drive pinion front bearing inner race.

13. At this point of the reassembly, adjust the drive pinion preload (turning torque) by following this procedure:

a. Without the oil seal installed insert the drive pinion into the gear carrier and then install from the front side of the carrier, the driver pinion spacer, drive pinion rear shim, drive pinion rear bearing inner race and the companion flange in that order.

b. Tighten the companion flange to 116–159 ft. lbs. on all engines except the 3.0L engine. On the 3.0L engine torque the companion flange to 137–181 ft. lbs. Measure the drive pinion turning torque without the

oil seal installed. The standard valve is 1.30–2.17 inch lbs. turning torque for all engines except the 3.0L engine. The standard valve is 3.47–4.34 inch lbs. turning torque for the 3.0L engine.

c. Adjust the turning torque by replacing the drive pinion rear shim(s) or the drive pinion spacer. Reduce number of drive pinion rear shims by replacing drive pinion spacer(s) as necessary.

d. Remove the companion flange and drive pinion once again.

14. Install drive pinion rear bearing inner race. Install oil seal into the gear carrier using suitable tools.

15. Install the drive pinion assembly and companion flange in the correct position. Tighten the companion flange to 116–159 ft. lbs. on all engines except the 3.0L engine. On the 3.0L engine torque the companion flange to 137–181 ft. lbs.

16. Measure the drive pinion turning torque with oil seal installed. The standard valve is 3.04–3.91 inch lbs. of turning torque for all engines except the 3.0L engine. The standard valve for the 3.0L engine is 5.21–6.08 inch lbs. of turning torque.

17. If not within the standard valve, check for faulty installation of the oil seal or wrong torque on the companion flange locking nut.

18. At this point of the reassembly,

adjust the differential gear backlash by following this procedure:

a. Install the side gears, side gear thrust spacers, pinion gear and pinion washers into the differential case. Temporarily install the pinion shaft. Do not drive the lock pin in place yet.

b. While locking the side gear with a wedge or equivalent, measure the differential gear backlash with a dial indicator on the pinion gear. The standard valve is 0–0.0030 in. and the service limit is 0.008 in. on all engines.

c. If the differential gear backlash exceeds the limit adjust the backlash by installing thicker side gear thrust spacers. If adjustment is not possible replace the side gears and pinion gears as a set.

19. Align the pinion shaft lock pin hole with the differential case lock pin hole.

20. Drive the lock pin in and stake the pin with a suitable tool in 2 different locations.

21. Install the drive gear onto the differential case with matchmarks in the correct position. Torque (with locking adhesive or equivalent on threads) drive gear attaching bolts to 58–65 ft. lbs. in a diagonal sequence for all engines.

22. Press fit the side bearing inner races to the differential case using suitable tools.

STEP 1

STEP 2

STEP 3

STEP 4

STEP 5

Adjustment of final drive backlash—front differential carrier

23. At this point of the reassembly, adjust the final drive gear backlash as follows:

a. Install the side bearing adjusting spacers (both sides same size-thin spacers as possible) to the side bearing outer races, then mount the differential case assembly into the gear carrier.

b. Push the differential case assembly to one side. Measure the clearance between the gear carrier and the side bearing adjusting spacer with a feeler gauge.

c. Measure the thickness of the side bearing adjusting spacers on a side. Select 2 pairs of spacers which correspond to that thickness plus $\frac{1}{2}$ of the clearance plus 0.002 in. and then install one pair each to the drive pinion side and the drive gear side.

24. Install the side bearing adjusting spacers and differential case assembly in the gear carrier.

25. Tap the side bearing adjusting spacers with a brass tool to position them to the side bearing outer races.

26. Align the mating marks on the gear carrier and the bearing caps and tighten the bearing caps to 40-47 ft. lbs. on all engines.

27. Attach a dial indicator to the ring gear teeth and measure the final drive gear backlash at 4 different locations. Final drive gear backlash standard value is 0.0043-0.0063 in. for all engines. Change the side bearing spacers as necessary for correct adjustment. When increasing the number of side bearing adjusting spacers, use the same number for each side and as few as possible.

28. Measure the ring gear runout in 2 or more locations. Runout should be 0.002 in. or less on all engines.

29. If necessary make a ring gear tooth pattern check. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

STEP 1

STEP 2

STEP 3

STEP 4

Inspection of rear differential carrier before disassembly

Rear Drive Axle

Inspection Before Disassembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. With the drive pinion locked in place, measure the final drive gear (ring gear) backlash with a dial indicator on the drive gear. Measure at 4 points or more on the drive gear.

3. The final drive gear backlash standard value for 2.0L, 2.4 and 2.6L engines is 0.0043-0.0063 in. The standard value for 3.0L engine is 0.0051-0.0071 in.

4. Measure the drive gear runout at the shoulder on the reverse side of the

Standard tooth contact pattern

- 1 Toe
- 2 Drive-side
- 3 Heel
- 4 Coast-side

Problem

Solution

Tooth contact pattern resulting from excessive pinion height

The drive pinion is positioned too far from the center of the drive gear.

Increase the thickness of the pinion height adjusting shim, and position the drive pinion closer to the center of the drive gear. Also, for backlash adjustment, position the drive gear farther from the drive pinion.

Tooth contact pattern resulting from insufficient pinion height

The drive pinion is positioned too close to the center of the drive gear.

Decrease the thickness of the pinion height adjusting shim, and position the drive pinion farther from the center of the drive gear. Also, for backlash adjustment, position the drive gear closer to the drive pinion.

drive gear the limit is 0.0020 in. on all engines.

5. On a conventional differential assembly the differential gear backlash must be checked. While locking the side gear with a wedge or equivalent, measure the differential gear backlash with a dial indicator on the pinion gear. The differential gear backlash (conventional) for the 2.0L, 2.4L and 2.6L engines standard valve is 0.0004–0.0030 in. The standard valve (conventional) for the 3.0L engine is 0–0.0030 in. The service limit is 0.008 in. on all engines.

6. Check the final drive gear tooth contact by the following steps:

a. Apply a thin uniform coat of machine blue or equivalent to both surfaces of the drive gear teeth.

b. Insert a tool between the differential carrier and the differential case and then rotate the companion flange by hand (once in normal direction and once reverse direction) while applying a load to the drive gear so that the revolution torque (about 2.5 ft. lbs.) is applied to the drive pinion.

c. If the drive gear is rotated too much, contact pattern will become unclear and difficult to read. If a correct pattern cannot be obtained (drive gear and pinion worn beyond allowable limits), replace the drive gear and the drive pinion as a set.

Disassembly and Assembly

1. Position the differential assembly in a suitable holding fixture. Remove the lock bolts and plates holding the side bearing nut in place.

2. Remove the side bearing nuts with the special adjusting tool spanner wrench No. MB990201 or equivalent.

3. Matchmark and remove the carrier caps and pry out the differential.

4. Pull off the differential side bearings. Be sure to keep the right and left bearings and shims separated. Remove side bearings inner and outer races.

5. Matchmark ring gear assembly and loosen the ring gear mounting bolts in diagonal sequence. Remove the ring gear.

6. Drive the pinion shaft lock pin out from the rear of the ring gear using a punch and remove the pinion shaft assembly.

7. Remove the thrust block, pinion gears and washers. Remove the side gears with their spacers. Keep left and right side gears and spacers separate. Remove the differential case.

8. On limited slip differential vehicles, remove limited slip differential case assembly.

9. Hold the end yoke (companion flange) and remove the self-locking

nut and washer. Matchmark for correct installation then remove the companion flange.

10. Tap the end of the drive pinion shaft (matchmark shaft assembly for correct installation) with a plastic hammer and force out the drive pinion

along with its adjusting shim, the rear inner race, the drive pinion spacer and the preload adjusting shim. The rear bearing inner race can be pressed off the pinion shaft.

11. Remove the front and rear pinion bearing outer races. The front inner

race should be removed with its oil seal. Remove the differential carrier case.

NOTE: Do not reuse the old oil seal. If the unit is to be assembled using no replacement parts except oil seals, the same spacers and shims can generally be used. If either pinion bearing or ring gear and drive pinion are being replaced, new shims should be used. Only replace the drive pinion and ring gear in matched sets.

12. Press the drive pinion front and rear bearing outer races into the differential carrier case. Make sure that the races do not tilt and that they sit fully in the case.

13. At this point of the reassembly, adjust the drive pinion height by following this procedure:

- a. Install special service tool MB991169 (use special adapter head tool C-4626 for 3.0L engine only) and drive pinion front and rear bear-

ing inner races to the gear carrier in the correct sequence.

b. Gradually tighten the nut of the special tool until the standard valve of the drive pinion turning torque is reached.

c. Measure the drive pinion turning torque without the oil seal installed. The standard valve for all engines is 3.5–4.3 inch lbs. of turning torque.

d. Mount the special service tool MB990552 in the side bearing seat of the gear carrier and then select a drive pinion height adjusting shim (keep rear shims to a minimum) of a thickness which corresponds to the gap between the special tools. Be sure to clean the side bearing seat thoroughly. When mounting the special tool be sure that the cut-out sections are in the correct position and also confirm that the tool is in close contact with the side bearing seat.

e. Install the selected drive pinion rear shim(s) to the drive pinion. Us-

ing special tool MB990802, press fit the drive pinion rear bearing inner race.

14. At this point of the reassembly, adjust the drive pinion preload (turning torque) by following this procedure:

a. Without the oil seal installed fit the drive pinion front shims between the drive pinion spacer and the drive pinion front bearing inner race.

b. Tighten the companion flange to 137–181 ft. lbs. on all engines. Measure the drive pinion turning torque without the oil seal installed. The standard valve is 3.5–4.3 inch lbs. turning torque for all engines.

c. Adjust the turning torque by replacing the drive pinion front shim(s) or the drive pinion spacer. Reduce number of drive pinion front shims by replacing drive pinion spacer as necessary.

d. Remove the companion flange and drive pinion once again.

15. Install drive pinion front bearing

inner race. Install oil seal into the gear carrier using suitable tools.

16. Install the drive pinion assembly and companion flange in the correct position. Torque the companion flange locking nut to 137–181 ft. lbs. on all engines.

17. Measure the drive pinion turning torque with oil seal installed. The standard valve is 5.6–6.5 inch lbs. of turning torque on all engines.

18. On limited slip differential vehicles, install limited slip differential case assembly.

19. At this point of the reassembly (conventional differential), adjust the differential gear backlash by following this procedure:

a. Install the side gears, side gear thrust spacers, pinion gear and pinion washers into the differential case. Temporarily install the pinion shaft. Do not drive the lock pin in place yet.

b. While locking the side gear with a wedge or equivalent, measure the differential gear backlash with a dial indicator on the pinion gear. The differential gear backlash for the 2.0L, 2.4L and 2.6L engines standard valve is 0.0004–0.0030 in. The standard valve for the 3.0L engine is 0–0.0030 in. The service limit is 0.008 in. on all engines.

c. If the differential gear backlash exceeds the limit adjust the backlash by installing thicker side gear thrust spacers. If adjustment is not possible replace the side gears and pinion gears as a set.

20. Install the thrust block. Align the pinion shaft lock pin hole with the differential case lock pin hole.

21. Drive the lock pin in and stake the pin with a suitable tool in 2 different locations.

22. Install the drive gear onto the differential case with matchmarks in the correct position. Torque (with locking adhesive or equivalent on threads) drive gear attaching bolts to 58–65 ft. lbs. on conventional and limited slip differentials in a diagonal sequence.

23. Press fit the side bearing inner races to the differential case using suitable tools.

24. Install the differential case assembly.

25. Install the carrier (bearing) caps with their mating marks in line with the marks on the carriers and finger tighten the 4 set bolts.

26. Install the side bearing nuts and tighten the carrier cap bolts to 40–47 ft. lbs. on all engines.

27. Screw in the side bearing nuts to adjust the final drive gear backlash. Each nut should be tightened to the state just before preloading of the side bearing.

28. Attach a dial indicator to the ring gear teeth and measure the final drive gear backlash in 4 different locations. The final drive gear backlash standard valve for 2.0L, 2.4 and 2.6L engines is 0.0043–0.0063 in. The standard valve for 3.0L engine is 0.0051–0.0071 in.

NOTE: If the backlash has to be adjusted, loosen the bearing nut on the back side of the ring gear and tighten the bearing nut on the teeth side by the same amount.

29. After adjusting backlash, tighten the bearing nuts $\frac{1}{2}$ pitch. One pitch is the space between 2 adjacent holes on the side of the bearing nut.

30. Again measure the backlash and install a 1 or 2 pronged lock plate whichever lines up with the bearing nut holes. Tighten the lock plate bolts to 11–16 ft. lb.

31. Measure the ring gear runout in 2 or more locations. Runout should be 0.002 in. or less on all engines.

32. If necessary make a ring gear tooth pattern check. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

6. Drive the pinion assembly from the carrier using suitable tools and brass punch. The outer (front) bearing will fall loose in the carrier, while the inner (rear) bearing will remain pressed on the drive pinion. Both races will remain in the carrier bores.

7. Remove rear bearing from the drive pinion by use of a press and tool J-22912-01 or equivalent.

8. Remove the oil seal and then drive the 2 outer races from the carrier by use of a brass drift and suitable tools.

9. Remove the ring gear bolts and separate the ring gear from the differential case. Use care when removing ring gear to prevent damage to differential case or ring gear. Do not force a chisel or other tools between the joining faces.

10. Drive out the pinion shaft lock pin with a long drift. It may be necessary to first break the stake on lock pin using a 0.020 diameter drill or equivalent.

11. Remove the pinion shaft with a drift pin and take out the pinion gears, side gears and thrust washers from the differential case.

NOTE: It is important to clean and assemble parts with care and to follow adjustment procedures. Axles which are contaminated with dirt or other foreign material, or which are incorrectly adjusted may be noisy and have short life. Be sure to use new seals, gaskets and flange nut when reassembling axle.

12. Wash the bearings in a suitable solvent. Then examine bearings carefully for wear, separation, cracks, seizure and other abnormal conditions. Replace bearings as necessary.

13. Check the ring gear and drive pinion teeth for wear, chipping, cracks, pitting and abnormal contact. Check the drive pinion splines for cracks, distortion and step wear. Replace parts if needed. Ring gear (torque for ring gear replacement is 73–87 ft. lbs. in diagonal sequence) and drive pinion come only in matched sets. If either item is defective, both parts must be replaced.

14. Check the pinion gears and side gears for wear, chipped teeth and separation and replace if needed.

15. Check and replace the thrust blocks if so equipped and thrust washers, if worn or damaged.

16. Check the lock pin for bending, dents and other abnormal conditions. Replace if necessary.

17. Check the side gear-to-axle shaft fit. Also check the fit of the pinion shaft to pinion gears. Examine the contact surfaces between side gears

ISUZU

Front Drive Axle

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Mark and remove the side bearing caps.

3. Remove the differential cage assembly. Keep the right and left side bearing races and shims if so equipped in separate groups for reinstallation in same positions.

4. Remove the differential side bearings from the case by using puller J-22888 and plug J-8107-2 or equivalent. Carefully record the thickness of each side bearing and each shim(s) removed for later use in reassembly and keep separated. Puller arms must not pull against roller cage. Use care to position legs against inner race. As bearing is being removed, check for free rotation of bearing. If bearing does not rotate freely, check position of puller legs.

5. Remove the companion flange nut while holding flange with suitable tools. Remove the flange assembly with puller if necessary.

Exploded view of front differential assembly—Isuzu

and differential case and between ring gear and case.

18. The standard valve for the clearance between the differential pinion and the cross pin is 0.002–0.005 in. and the service limit is 0.008 in.

19. The standard valve for the clearance between the side gear and the differential assembly is 0.001–0.004 in. and the service limit is 0.006 in.

20. The standard valve for play (backlash) in splines between the side gear and the axle shaft is 0.001–0.006 in. and the service limit is 0.010 in.

21. Install the side gears and thrust washers in the differential case.

22. Position the pinion gears 180 degrees apart. Roll gears into position,

making sure they are in alignment, to allow installation of the pinion shaft.

23. Place the thrust block if equipped between the pinion gears and drive the pinion shaft into position. Make sure that the lock pin hole in cross shaft aligns with the hole in the case.

24. Measure the amount of backlash between the differential gears and the pinion gears. If the backlash is greater than 0.001–0.003 in., make the necessary adjustment with the thrust washers.

25. Install lock pin into cross shaft and stake the cage to prevent loosening of the pin.

26. Apply Loctite or equivalent to the threaded portion of the bolts. Install

the ring gear in position on the differential case. Tighten the bolts (always use new retaining bolts) in diagonal sequence to 73–87 ft. lbs.

27. To set pinion depth install the drive pinion front and rear bearing outer races into carrier bores. Use drive handle J-8092 with J-24256 for front bearing race and J-24252 or equivalent for rear bearing race.

28. Lubricate and position the front and rear bearings to be used for final assembly into their respective races.

29. Install gauging plate J-23597-7 and preload stud and pilot J-23597-9 or their equivalent through front and rear bearings and tighten nut snugly.

30. Rotate the bearings to insure

Shim selection chart—Isuzu front and rear conventional drive axles

Adjustment of drive pinion mounting distance

proper seating and tighten locknut until 20 inch lbs. of torque are required to rotate new bearings; 8-10 inch lbs. for used bearings.

31. Place discs J-23597-8 onto arbor J-23597-1 or equivalent and place tool into position in side bearing bores.

32. Install bearing caps and torque to 65-72 ft. lbs.

33. Mount dial indicator J-8001 or equivalent on arbor post and preload dial $\frac{1}{2}$ revolution. Tighten indicator in this position.

34. Position the indicator plunger on the gauge plate and slowly swing across until the highest reading is obtained. Zero the indicator on the highest reading of the gauge plate.

35. Carefully swing the plunger off the gauge plate. Note the indicator reading. Recheck to verify the reading. Record the number the dial indicator needle points to. The reading on the dial is the correct dimension for the rear pinion depth shim. Convert the dial indicator reading (inches) to pinion marking (depth code) specification.

36. Record pinion depth code on the head of the drive pinion. The number indicates a necessary change in the pinion mounting distance. A plus number indicates the need for a greater mounting distance (which can be achieved by decreasing the shim thickness). A minus number indicates the need for a smaller mounting distance (which can be achieved by increasing the shim thickness). If examination reveals no pinion depth code, the pinion is nominal. Determine the proper shim variation to compensate for plus or minus markings.

37. Place the shim on the drive pinion, then install the rear bearing, using J-6133-01 or equivalent. Do not press on roller cage press only on inner race.

38. To set pinion bearing preload place the drive pinion and spacer (always use new spacer) into the carrier.

39. Lubricate, then position the front bearing to be used in final assembly into the carrier. Install new oil seal.

40. Install companion flange to drive pinion. Apply hypoid lubricant to pinion threads. Install new pinion nut and torque to 130-202 ft. lbs. using J-8614-01 or equivalent to hold companion flange.

41. Rotate drive pinion to insure that bearings are seated. Measure the bearing preload by using a torque wrench. Note the scale reading required to rotate the flange.

42. Continue tightening until the correct starting torque is obtained. The standard valve for starting torque is 5.6-9.9 inch lbs. The pinion nut should be tightened only in small in-

crements and the scale should be checked after each small amount of tightening. Exceeding preload specifications may compress the collapsible spacer too far and require its replacement.

43. Install the side bearings to be used in final assembly onto the differential case. Do not install shims at this time. Use J-24244 or equivalent for the first bearing installation.

44. Support case on plug J-8107-2 or equivalent for opposite bearing installation.

45. Install the differential cage assembly into carrier bores.

46. Using 2 sets of feeler gauges, insert a feeler gauge of sufficient thickness between each bearing outer race and the carrier to remove all endplay.

Make certain the feeler gauge is pushed to the bottom of the bearing bores.

47. Install a dial indicator on the carrier so that the stem of the tool is at a right angle to a tooth on the ring gear.

48. Adjust feeler gauge thickness from side to side until the gear backlash is 0.005-0.007 in.

49. With zero endplay and correct backlash established, remove the feeler gauge. Determine the thickness of the shims (always use new shims) required and add 0.002 in. to each shim pack to provide side bearing preload.

50. Remove the case from the carrier. Carefully remove both side bearings. Install shims as determined behind each bearing, install bearings onto case.

51. Install case onto carrier, tapping carefully into place. Install side bearing caps in original position. Tighten to 65-79 ft. lbs.

52. Measure the run out of the ring gear. If the run out exceeds 0.002 in., correct by replacement.

53. Apply a thin coat of prussian blue or equivalent to the faces of 7-9 teeth of the ring gear. Check the impression of the contact on the ring gear teeth and make the necessary adjustments.

54. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

Rear Drive Axle

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture. Take tooth pattern check this check will help determine what service should be performed on the differential components.

2. Mark and remove the side bearing caps.

3. Remove the differential cage assembly. Keep the right and left side

bearing races and shims if so equipped in separate groups for reinstallation in same positions.

4. Remove the differential side bearings from the case by using puller J-22888 and plug J-8107-2 or equivalent (some special tools may be different on the limited slip differential carrier). Carefully record the thickness of each side bearing and each shim(s) removed for later use in reassembly and keep separated. Puller arms must not pull against roller cage. Use care to position legs against inner race. As bearing is being removed, check for free rotation of bearing. If bearing does not rotate freely, check position of puller legs.

5. Remove the companion flange nut while holding flange with suitable tools. Remove the flange assembly with puller if necessary.

6. Drive the pinion shaft assembly from the carrier using suitable tools and brass punch. The outer (front) bearing will fall loose in the carrier, while the inner (rear) bearing will remain pressed on the drive pinion. Both races will remain in the carrier bores.

7. Remove rear bearing from the drive pinion by use of a press and tool J-22912-01 or equivalent on conventional differential carrier. On limited slip differential carrier use special tool J-37452 and a press.

8. Remove the oil seal and then drive the 2 outer races from the carrier by use of a brass drift and suitable tools.

9. Remove the ring gear bolts (diagonal pattern) and separate the ring gear from the differential case. Use care when removing ring gear to prevent damage to differential case or ring gear. Do not force a chisel or other tools between the joining faces.

10. At this point of the reassembly, check the amount of backlash before removal. The standard valve for backlash is 0.001-0.003 in. for conventional differential. The standard valve for backlash is 0.005-0.007 in. for limited slip differential.

11. On conventional differential carrier drive out the pinion shaft lock pin with a long drift. It may be necessary to first break the stake on lock pin using a 0.020 diameter drill or equivalent.

12. On conventional differential carrier remove the pinion shaft with a drift pin and take out the pinion gears, side gears, thrust block and thrust washers from the differential case.

13. On limited slip differential remove the limited slip differential carrier assembly.

14. Wash the bearings in a suitable solvent. Then examine bearings carefully for wear, separation, cracks, sei-

zure and other abnormal conditions. Replace bearings as necessary.

15. Check the ring gear and drive pinion teeth for wear, chipping, cracks, pitting and abnormal contact. Check the drive pinion splines for cracks, distortion and step wear. Replace parts if needed. Ring gear and drive pinion come only in matched sets. If either item is defective, both parts must be replaced.

16. Check the pinion gears and side gears for wear, chipped teeth and separation and replace if needed.

17. Check and replace the thrust blocks on conventional differential and thrust washers, if worn or damaged.

18. On conventional differential check the lock pin for bending, dents and other abnormal conditions. Replace if necessary.

19. Check the clearance between pinion gear and cross pin. The standard valve for the clearance between the differential pinion and the cross pin is 0.002–0.005 in. and the service limit is 0.008 in. on both differential carriers.

20. Check the clearance between the side gear and differential box. The standard valve for the clearance between the side gear and the differential assembly is 0.001–0.004 in. and the service limit is 0.006 in. on conven-

tional carrier. The standard valve for the clearance between the side gear and the differential assembly is 0.002–0.004 in. and the service limit is 0.006 in. on limited slip differential carrier.

21. Check the play in splines between the side gear and axle shafts. The standard valve for play (backlash) in splines between the side gear and the axle shaft is 0.001–0.006 in. and the service limit is 0.010 in. on the conventional differential. The standard valve for play in splines between the side gear and the axle shaft is 0.03–0.15 in. and the service limit is 0.010 in. on the limited slip differential.

22. Install the side gears and thrust washers in the differential case. Position the pinion gears 180 degrees apart. Roll gears into position, making

sure they are in alignment, to allow installation of the pinion shaft.

23. Place the thrust block on conventional differential between the pinion gears and drive the pinion shaft into position. Make sure that the lock pin hole in cross shaft aligns with the hole in the case.

24. Measure the amount of backlash between the differential gears and the pinion gears. The standard valve is 0.001–0.003 in. on conventional differential and 0.005–0.007 in. on limited slip differential. Make the necessary adjustment with the thrust washers.

25. Install lock pin into cross shaft and stake the cage to prevent loosening of the pin.

26. Apply Loctite or equivalent to the threaded portion of the bolts. Install

the ring gear in position on the differential case. Tighten the bolts (always use new retaining bolts) in diagonal sequence to 73–87 ft. lbs. on conventional and limited slip differentials.

27. To set pinion depth install the drive pinion front and rear bearing outer races into carrier bores. Use drive handle J-8092 with J-24256 (conventional carrier) or J-37262 for limited slip differential carrier for front bearing race and J-24252 (conventional carrier) and J-24252 for limited slip differential carrier for rear bearing race.

28. Lubricate and position the front and rear bearings to be used for final assembly into their respective races.

29. Install gauging plate J-23597-7 and preload stud and pilot J-23597-9

or their equivalent through front and rear bearings and tighten nut snugly. On limited slip differential carriers special tool numbers may change.

30. Rotate the bearings to insure proper seating and tighten locknut until 20 inch lbs. of torque are required to rotate new bearings; 8–10 inch lbs. for used bearings.

31. Place discs J-23597-8 onto arbor J-23597-1 or equivalent (special tool numbers may change on limited slip differential carrier) and place tool into position in side bearing bores. Install bearing caps and torque to 65–72 ft. lbs. on conventional carrier. Torque the bearing caps 73–87 ft. lbs. on limited slip differential carrier.

32. Mount dial indicator J-8001 or equivalent on arbor post and preload

dial $\frac{1}{2}$ revolution. Tighten indicator in this position.

33. Position the indicator plunger on the gauge plate and slowly swing across until the highest reading is obtained. Zero the indicator on the highest reading of the gauge plate. Repeat procedure if necessary for correct readings.

34. After zero setting is obtained carefully swing the plunger off the gauge plate. Note the indicator reading. Recheck to verify the reading. Record the number the dial indicator needle points to. The reading on the dial is the correct dimension for the rear pinion depth shim. Convert the dial indicator reading (inches) to the correct pinion marking (depth code) specification.

35. Record pinion depth code on the head of the drive pinion. The number indicates a necessary change in the pinion mounting distance. A plus number indicates the need for a greater mounting distance (which can be achieved by decreasing the shim thickness). A minus number indicates the need for a smaller mounting distance (which can be achieved by increasing the shim thickness). If examination reveals no pinion depth code, the pinion is nominal. Determine the proper shim variation to compensate for plus or minus markings.

36. Place the shim on the drive pinion with chamfered side toward the pinion head then install the rear bearing, using J-6133-01 or equivalent. Do not press on roller cage press only on inner race.

37. To set pinion bearing preload place the drive pinion and spacer (always use new spacer) into the carrier.

38. Lubricate, then position the front bearing to be used in final assembly into the carrier. Install new oil seal.

39. Install companion flange to drive pinion. Apply hypoid lubricant to pinion threads. Install new pinion nut and torque to 130-202 ft. lbs. using J-8614-01 or equivalent to hold companion flange. On limited slip differential carrier torque new pinion nut to 180-217 ft. lbs. using suitable tools to hold flange.

40. Rotate drive pinion to insure that bearings are seated. Measure the bearing preload by using a torque wrench. Note the scale reading required to rotate the flange.

41. Continue tightening until the correct starting torque is obtained. The standard value for starting torque is 5.6-9.9 inch lbs. on conventional differential and 6.1-11.3 inch lbs. on limited slip differential carrier. The pinion nut should be tightened only in small increments and the scale should be checked after each small amount of tightening. Exceeding preload specifications may compress the collapsible spacer too far and require its replacement.

42. Install the side bearings to be used in final assembly onto the differential case. Do not install shims at this time. Use J-24244 or equivalent for the first bearing installation (on limited slip differential carrier special tools numbers may be different).

43. Support case on plug J-8107-2 or equivalent for opposite bearing installation.

44. Install the differential cage assembly into carrier bores.

45. Using 2 sets of feeler gauges, insert a feeler gauge of sufficient thickness between each bearing outer race and the carrier to remove all endplay. Make certain the feeler gauge is pushed to the bottom of the bearing bores.

46. Install a dial indicator on the carrier so that the stem of the tool is at a right angle to a tooth on the ring gear.

47. Adjust feeler gauge thickness from side to side until the gear backlash is 0.005-0.007 in. on conventional differential and 0.006-0.008 in. on limited slip differential.

48. With zero endplay and correct backlash established, remove the feeler gauge. Determine the thickness of the shims (always use new shims) required and add 0.002 in. to each shim pack to provide side bearing preload.

49. Remove the case from the carrier. Carefully remove both side bearings. Install shims as determined be-

hind each bearing, install bearings onto case.

50. Install case onto carrier, tapping carefully into place. Install side bearing caps in original position. Tighten bearing caps to 65-79 ft. lbs. on conventional differential carrier and 73-87 ft. lbs. on limited slip differential carrier.

51. Measure the run out of the ring gear. If the run out exceeds 0.002 in., correct by replacement. Apply a thin coat of prussian blue or equivalent to the faces of 7-9 teeth of the ring gear. Check the impression of the contact on the ring gear teeth and make the necessary adjustments.

52. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

MAZDA

Front and Rear Drive Axles

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Apply identification punch marks on the carrier, the differential bearing cap and adjusters for correct reassembly.

3. Remove the adjuster lock plates.

4. Loosen the bolts securing the bearing cap and slowly back off the adjuster slightly to relieve the preload.

5. Remove the nuts, bearing caps and adjusters. Keep each bearing cap with its own adjuster.

6. Lift out the differential assembly and keep each bearing outer race with its own bearing.

7. If the differential bearings are to be replaced, mark for correct installation and remove using a suitable puller.

8. Remove the bolts (in diagonal pattern) and washers retaining the ring gear to the case.

9. Remove the ring gear. On conventional differential position the assembly in a vise or equivalent and remove the lock pin (tap out toward the ring gear side) with a suitable punch (0.16 in. diameter size).

10. On conventional differential remove the pinion shaft and the thrust block. Rotate the differential pinion gears 90 degrees and remove. Remove the differential side gears and thrust washers.

11. On limited slip differential re-

move the limited slip differential carrier assembly.

12. Using a holding tool, steady the companion flange and remove the nut.

13. Remove the companion flange using suitable puller.

14. Remove the front bearing, drive pinion and rear bearing from the carrier, which may require tapping with a plastic mallet or equivalent. Guide the pinion assembly to avoid damage to any component.

15. Remove the oil seal and the front bearing.

16. The pinion bearing outer races (cups) can be removed (mark for correct installation) from the carrier by tapping out using a drift in the slots provided.

17. Remove the rear bearing from the pinion (support the pinion during bearing removal) using suitable press and separator plate.

18. Check the drive pinion for dam-

aged or worn teeth, damaged bearing journals or splines. Inspect the ring gear again for worn or chipped teeth. If any of the above conditions are found, replace both drive pinion and ring gear as a set.

19. Inspect bearing cones and cups and replace any showing wear, flaking or damage. Replace only in sets. Do not use an old cup with a new bearing or an old bearing with a new cup.

20. Check the companion flange carefully for cracks or worn splines. If either exist, the part should be replaced. Check for rough or scratched oil seal contact surface. If only slight scratches appear, it may be possible to repair with crocus cloth. Otherwise, replace it. Be sure to use a new oil seal when reassembling the carrier.

21. On conventional differential assembly the side gears, thrust washers, thrust block, pinion gears, pinion shaft and lock pin. After installing lock

pin stake pin so pin cannot come out of gear case.

22. On conventional differential assembly press the side bearings (correct location) onto the gear case using suitable tools. Adjust the backlash of the side gears and pinion gear as follows:

a. Position a dial indicator against the pinion gear. Secure one of the side gears.

b. Move the pinion gear and measure the backlash at the end of the pinion gear.

c. The standard valve for backlash is 0–0.004 in. on all vehicles. If backlash exceeds the standard valve use suitable thrust washer to adjust.

23. On conventional and limited slip differential carriers apply thread locking compound install ring gear to differential assembly. Torque the retaining bolts to 51–61 ft. lbs. all vehicles in a diagonal pattern.

24. Press fit the companion flange side bearing outer races using bearing installer set.

25. Press fit the ring gear side bearing outer races using bearing installer set.

NOTE: Special tools are required to check and adjust the pinion height, these include a drive pinion model tool 498531565, a pinion height adjustment gauge body tool 490727570 and a gauge block tool 400305555.

26. At this point of the reassembly, adjust the pinion height as follows:

a. Fit the spacer, rear bearing and collar onto the drive pinion model. Secure the collar with an O-ring and install in the assembly in the carrier.

b. Attach the front bearing, collar, companion flange, washer and nut to the drive pinion model. Use the same spacer and nut which were removed at disassembly. Be careful to install collars in their correct position facing in the correct direction.

c. Tighten the nut until the drive pinion model can be turned by hand without any apparant play.

d. Install a dial indicator on the pinion height adjustment gauge body. Place the gauge block on top of the drive pinion model and then set the pinion height adjustment gauge body on top of the gauge block.

e. Place the measuring probe of the dial indicator so that it contacts the location where the side bearing is installed in the carrier. Zero and set up the indicator to measure the lowest point. Measure both the left and right sides. Add the 2 values (right and left side readings) and divide the total by 2. The standard valve of this specification is 0 in. on all vehicles. Install correct spacer as necessary to adjust pinion height.

27. Install the correct spacer(s) on the pinion shaft (facing in the proper direction) and press the bearing on the pinion shaft.

28. Install the drive pinion, spacer, front bearing, collapsible spacer and companion flange in the carrier and temporarily tighten the locknut. Do Not install the pinion oil seal at this time.

29. At this point of the reassembly, adjust preload of the drive pinion as follows:

a. Rotate the companion flange by hand to seat the bearing.

b. Use a torque wrench to tighten the locknut. Tighten slowly until the required preload drag of 7.8-12.2 inch lbs. is reached with a locknut torque of 94-130 ft. lbs. for all applications except MPV vehicle.

STEP 1

STEP 2

Adjustment of drive pinion height

c. On MPV vehicle, slowly tighten until the preload drag of 11.3-15.6 inch lbs. is reached with a locknut torque of 94-210 ft. lbs.

d. If the specified preload cannot be maintained within the locknut tightening range, install a new collapsible spacer and repeat the process if necessary.

e. On all applications except MPV vehicle remove the locknut and flange. Install the pinion seal, flange and new locknut. Tighten the locknut to the ft. lbs. specification torque giving the correct preload.

f. On MPV vehicle, remove the locknut and flange. Install the pinion seal, flange and new locknut. Retighten the locknut to the preload drag of 13.9-18.2 inch lbs. is reached with a locknut torque of 94-210 ft. lbs.

30. Install the differential gear assembly in the carrier. Note the identification marks on the adjusters and install each to its respective side. Install the bearing caps making sure that the identification marks on the caps correspond with those on the carrier and install the bolts.

31. Loosely tighten the bearing cap mounting bolts and completely tighten the adjustment screws by hand. Then, while turning the ring gear, alternately tighten the left and right adjustment screws using a suitable tool.

32. At this point of the reassembly, adjust the drive pinion and ring gear backlash and side bearing preload as follows:

a. Mark the ring gear at 4 points at approximately 90 degree intervals and mount a dial indicator to the carrier flange so that the feeler comes in contact at right angles with one of the ring gear teeth.

b. Turn both bearing adjusters equally until backlash becomes (standard valve for all vehicles) 0.0035-0.0043 in.

c. Check the backlash at the other 3 marked points and make sure that minimum backlash is more than 0.002 in. and the difference in the valve of the maximum and minimum backlash is less than 0.0028 in.

d. After adjusting the backlash, tighten the adjustment screws equally until the distance between both pilot sections on the bearing caps becomes the standard distance. The standard distance is 7.3004-7.3031 in. for B2000 (2WD) and B2200 (2WD) rear axle assemblies and B2600 (4WD) front axle assembly. The standard distance is 8.0484 in. plus or minus 0.028 in. for B2600 (2WD and 4WD) rear axle assemblies and the MPV rear axle assembly. When adjusting the differential bearing preload, care must be taken not to affect the backlash of the drive pinion gear and ring gear.

Adjustment of drive pinion and ring gear backlash

Toe contact

Flank contact

Heel contact

Face contact

Differential tooth contact pattern—Mazda

33. Tighten the bearing caps to the standard valve. The standard valve for B2000 (2WD) and B2200 (2WD) rear axles and B2600 (4WD) front axle assembly is 27–38 ft. lbs. The standard valve for B2600 (2WD and 4WD) rear axle assemblies is 41–59 ft. lbs. The standard valve for the MPV vehicle is 51–61 ft. lbs.

34. Install the adjuster lock plates.

35. Coat both surfaces of 6–8 teeth of the ring gear uniformly with a thin coat of red lead or equivalent.

36. While moving the ring gear back and forth by hand, rotate the drive pinion several times and check the tooth contact.

37. If pattern is not correct readjust the pinion height then the backlash.

38. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

R200A models. The standard valve is 0.0030 in. of runout for R180 model.

5. Using suitable equipment check differential tooth contact for correct pattern as follows:

a. Thoroughly clean ring gear and drive pinion teeth.

b. Sparingly apply red lead or equivalent to 3 or 4 teeth of ring gear drive side.

c. Hold companion flange steady by hand and rotate the ring gear in both directions.

d. Interrupt contact marks left on the ring gear assembly. Gear tooth contact pattern check is necessary to verify correct relationship between ring gear and drive pinion.

6. On R180 model, check backlash of side gear. Using a thickness gauge, measure clearance between side gear and differential case. The standard valve is 0.006 in. of side gear clearance.

10. Remove front oil seal and pinion front bearing inner cone.

11. Remove the pinion front and rear bearing outer races with brass drift from housing.

12. Remove the pinion rear bearing inner cone and drive pinion adjusting washer. Remove rear bearing with suitable press and separator plate.

13. Remove side bearing inner race assembly with a puller from the differential carrier. Mark all parts for correct installation.

14. Remove ring gear by spreading out lock straps if so equipped and loosening ring gear bolts in a criss-cross pattern. Remove all retaining bolts.

15. Tap ring gear off gear case using a soft hammer or equivalent. Tap evenly all around to keep ring gear from binding.

16. On R180A model, separate the left and right differential case halves.

17. On R180 and R200A models, drive out pinion mate shaft lock pin with drift pin from ring gear side.

18. Draw out pinion mate shaft and thrust block if so equipped. Rotate pinion mate gears out of case and remove side gears and thrust washers. Put marks on gears and thrust washers so that they can be reinstalled in their original positions from which they were removed.

19. Clean disassembled parts completely. Repair or replace any damaged or faulty parts. If replacing drive pinion or ring gear, replace with a new hypoid gear as a set.

20. On R180A model, assemble the differential carrier as follows:

a. Measure the clearance between the side gear thrust washer and differential case.

b. The standard valve for the clearance between side gear thrust washer and differential case is 0.0039–0.0079 in. The clearance can be adjusted with side gear thrust washer.

c. Apply gear oil to gear tooth surfaces and thrust surfaces and check to see they turn properly.

NISSAN

Front Drive Axle

Inspection Before Disassembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Check total preload by turning drive pinion in both directions several times to set bearings. Using torque wrench or equivalent measure valve. The standard valve for model R180 and R180A differential carriers is 8.7–20 inch lbs. of turning torque. The standard valve for model R200A is 10.9–20.4 inch lbs. of turning torque.

3. Check the backlash of ring gear with a dial indicator at several points. The standard valve for ring gear to drive pinion backlash is 0.0051–0.0071 in., on all vehicles.

4. Check runout of ring gear with a dial indicator. The standard valve is 0.0020 in. of runout for R180A and

Disassembly and assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. On R180A and R200A models remove the extension tube and differential side shaft assembly. Remove differential side flanges.

3. Matchmark side retainers and shims (some have retaining bolts) with paint to ensure that they are replaced in proper position during reassembly.

4. Remove the differential case from the final drive housing.

5. Remove the side bearing outer races. Mark all parts for correct installation.

6. Remove the side bearing oil seals using suitable puller.

7. Attach a flange holding wrench or equivalent to hold flange from turning. Loosen the drive pinion nut.

8. Remove the companion flange using suitable puller.

9. Remove the drive pinion together with pinion rear bearing inner cone, drive pinion bearing spacer and pinion bearing adjusting washer.

Exploded view of front differential assembly - Nissan

25 DRIVE AXLES IMPORT

STEP 1

STEP 2

STEP 3

Drive pinion gear preload adjustment

d. Install the left and right differential case halves torque retaining bolts to 47-54 ft. lbs. Position the differential case on the ring gear. Apply Locktite or equivalent and tighten ring gear retaining bolts to (criss-cross fashion) 76-90 ft. lbs.

e. Press fit side bearings on the differential case using suitable press and tools.

21. On R180 and R220A models, assemble the differential carrier as follows:

a. Install pinion mate gears, side gears and thrust washers into differential case.

b. Fit pinion mate shaft and thrust block.

c. Adjust clearance between rear face of side gear and thrust washer by selecting side gear thrust washer. The standard valve for clearance on R200A model is 0.0039-0.0079 in.

specification. The standard valve for clearance on R180 model is 0-0.006 in. specification.

d. Install pinion mate shaft lock pin using a punch. Make sure lock pin is flush with case.

e. Apply gear oil to gear tooth surfaces and thrust surfaces and check to see they turn properly.

f. On R180 model, place ring gear on differential case and install new lock straps and bolts. Tighten bolts to 88-98 ft. lbs. in a criss-cross fashion, lightly tapping bolt head with a hammer. Then bend up lock straps to lock the bolts in place.

g. Press fit front and rear bearing outer races using suitable tools. Make sure that the bearing races are seated squarely in their respective bores.

h. On R200A model, position the differential case on the ring gear. Apply Locktite or equivalent and tighten ring gear retaining bolts to (criss-cross fashion) 98-112 ft. lbs. Press fit side bearings on the differential case using suitable press and tools.

22. Press fit pinion front and rear bearing outer races into housing with suitable tools on all models as necessary.

23. On all models select pinion bearing adjusting washer and drive pinion bearing spacer as follows:

a. Make sure all parts are clean and that bearings are well lubricate. Assemble the pinion gear bearings into the pinion preload shim selector tool J-34309 or equivalent. Make sure that the front and rear bearings are in the correct position on the special tool (rear bearing first).

b. Install the pinion preload shim selector tool or equivalent into the final drive axle housing. Make sure

that the pinion height gauge will make a full turn and tighten the 2 sections by hand. Turn the special tool with bearings installed on it several times to seat the bearings.

c. Measure the turning torque at the end of the tool with a torque wrench. The standard valve for the R180A model is 5.2-8.7 inch lbs. The standard valve for the R200A model is 8.7-11.3 inch lbs. The standard valve for the R180 model is 7.8-14.8. inch lbs.

d. Place correct pinion height adapter (each model has different pinion height adapter) onto the gauge plate and tighten it by hand.

e. Insert the pinion bearing adjusting spacer squarely into the recessed portion of the correct special tool. Select the correct thickness of the pinion bearing preload adjusting washer using a standard valve plus the distance between spacer and gauge anvil tool. The exact measurement you get with the standard valve and distance between spacer and special tool is the thickness of the adjusting washer required. The standard valve for the R180A model is 0.24 in. and 0.138 in. for the R200A model. The standard valve is 0.118 in. for R180 model.

f. On R180A model position the side bearing discs tool J-25269-4 and arbor firmly in the side bearing bores. On R200A model install tool as previous described and torque the side bearing cap bolts to 65-72 ft. lbs.

g. Select the correct standard pinion height adjusting washer thickness using a standard valve plus the distance between pinion height adapter tool and the arbor. The standard valve for the R180A and R200A models is 0.12 in. On R180

Pinion Head Height Number	Add or Remove from the Standard Pinion Height Washer Thickness Measurement
-6	Add 0.06 mm (0.0024 in)
-5	Add 0.05 mm (0.0020 in)
-4	Add 0.04 mm (0.0016 in)
-3	Add 0.03 mm (0.0012 in)
-2	Add 0.02 mm (0.0008 in)
-1	Add 0.01 mm (0.0004 in)
0	Use the selected washer thickness
+1	Subtract 0.01 mm (0.0004 in)
+2	Subtract 0.02 mm (0.0008 in)
+3	Subtract 0.03 mm (0.0012 in)
+4	Subtract 0.04 mm (0.0016 in)
+5	Subtract 0.05 mm (0.0020 in)
+6	Subtract 0.06 mm (0.0024 in)

Drive pinion gear height chart—Nissan

model use the appropriate service tool for this operation and measure the thickness of the lead washer.

h. Correct the pinion height washer size by referring to the pinion head number. There are 2 numbers on the pinion gear. The first one refers to the pinion and ring gear as a matched set and the number should be the same on the ring gear. The second number is the pinion head height number and it refers to the ideal pinion height for proper operation. Use this number to determine the correct pinion height washer. Select the correct pinion height washer and remove the special tools with pinion bearings from housing.

24. Install pinion height adjusting washer in drive pinion, bevel side toward gear and press fit rear bearing inner race in it, using press and special tools.

25. Lubricate front bearing with gear oil and place it in gear housing.

26. Carefully fit a new oil seal into carrier. Make sure oil seal is flush with end of carrier and apply multi-purpose grease into cavity between lips.

27. Install the drive pinion bearing spacer, pinion bearing adjusting washer and drive pinion in housing.

28. Install companion flange into drive pinion by tapping with a soft hammer or equivalent.

29. Hold companion flange and temporarily tighten pinion nut, until there is no axial play. Ascertain that threaded portion of drive pinion and pinion nut are free from oil or grease. Tighten pinion nut by degrees to the specified preload while checking the preload with torque wrench. Preload with oil seal is 7.8–14.8 inch lbs. for R180 and R180A models and 10.0–15.2 inch lbs. for the R200A model.

30. When checking preload, turn drive pinion in both directions several times set bearing rollers. After preload is reached torque pinion nut to 123–145 ft. lbs. on R180 and R180A models and 137–217 ft. lbs. on R200A model. Preload and final pinion nut torque **MUST** both be attained for correct operation of axle unit.

31. On the R180 and R180A models select the side retaining washer as follows:

a. Make sure all parts are cleaned and well lubricated with automatic transmission fluid.

b. Install the differential carrier and side bearing assembly into the housing.

c. Install all old bearing preload shims onto side bearing retainer. Install both bearing retainers onto housing and torque retaining bolts to 6.5–7.2 ft. lbs.

d. Turn carrier several times to seat bearings. Measure the carrier turning torque with a tool at the ring gear retaining bolt. The standard valve of pulling force at the ring gear bolt is 7.7–8.8 ft. lbs. Add or subtract shims as necessary. Increase shim thickness to decrease turning torque and decrease shim thickness to increase turning torque. Record correct shim(s) thickness and remove carrier and bearings.

32. On the R220A model select the side retaining washer as follows:

a. Make sure all parts are cleaned and well lubricated with automatic transmission fluid.

b. Install the differential carrier with side bearings and bearing races installed into gear housing.

c. Install side bearing spacer on the ring gear end of the carrier.

d. Install old preload shims using suitable tools on the carrier end opposite the ring gear.

e. Install side bearing caps and torque retaining bolts to 65–72 ft. lbs.

f. Turn carrier several times to seat bearings. Measure the carrier turning torque with a tool at the ring gear retaining bolt. The standard valve of pulling force at the ring gear bolt is 7.7–8.8 ft. lbs. Add or subtract shims as necessary. Increase shim thickness to decrease turning torque and decrease shim thickness to increase turning torque. Record correct shim(s) thickness and remove carrier and bearings.

33. On R180 and R180A model, press fit side bearing outer race into side retainer using suitable tools.

34. Install oil seals. Install differential case assembly. Place side retainer (correct marked position) adjusting shims and O-ring on side retainer and install on housing.

35. On R200A model install differential case assembly with side bearings outer races into housing. Insert the correct bearing adjusting washers between side bearings and housing. Drive in side bearing spacer with suitable tools.

36. Align mark on bearing caps and install caps torque to 65–72 ft. lbs.

37. Measure the ring gear to drive pinion backlash with a dial indicator. The standard valve is 0.0051–0.0071 in. If backlash is too small, decrease thickness of right shim and increase thickness of left shim by the same amount. If backlash is too great reverse the above procedure. Never change the total amount of shims as it will change the bearing preload.

38. Check total preload with torque

wrench, turn drive pinion several times in both directions to set bearings. The standard valve for total preload is 8.7–20.0 inch lbs. for R180 and R180A models. The standard valve for total preload is 10.9–20.4 inch lbs. for R200A model.

39. On R180 and R180A models if preload is too great, add the same amount of shims to each side. If preload is too small, remove the same amount of shims from each side. Never add or remove a different number of shims for each side as it will change ring gear to drive pinion backlash.

40. On R200A model if preload is too great, remove the same amount of shims from each side. If preload is too small, add the same amount of shims to each side. Never add or remove a different number of shims for each side as it will change ring gear to drive pinion backlash.

41. Recheck ring gear to drive pinion backlash. Check runout of ring gear the standard valve for R180 and R180A models is 0.0031 in. and 0.0020 in. for the R200A model.

42. Check tooth contact pattern as necessary.

43. Install rear cover and gasket on all models. Install extension tube and differential side shaft assembly on R180A and R200A models. Install the side flange in correct position on R180 model.

Rear Drive Axle

Inspection Before Disassembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Check total preload by turning drive pinion in both directions several times to set bearings. Using torque wrench or equivalent measure valve. The standard valve for model H190A and C220 models is 10–19 inch lbs. of turning torque. The standard valve for H233B model is 8.7–17.4 inch lbs. of turning torque.

3. Check backlash of ring gear with a dial indicator at several points. The standard valve for models H190A and C220 ring gear to drive pinion backlash is 0.0051–0.0071 in. and 0.0059–0.0079 in. for H233B model.

4. Check runout of ring gear with a dial indicator. The standard valve is 0.0031 in. of runout for all models.

5. Using suitable equipment check differential tooth contact for correct pattern as follows:

a. Thoroughly clean ring gear and drive pinion teeth.

b. Sparingly apply red lead or equivalent to 3 or 4 teeth of ring gear drive side.

Exploded view of limited slip differential assembly—Nissan

c. Hold companion flange steady by hand and rotate the ring gear in both directions.

d. Interrupt contact marks left on the ring gear assembly. Gear tooth contact pattern check is necessary to verify correct relationship between ring gear and drive pinion.

6. On all models, check backlash of side gear. Using a thickness gauge, measure clearance between side gear thrust washer and differential case. The standard valve is 0.039–0.0079 in. of side gear clearance.

Disassembly and assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Matchmark side bearing caps and shims if so equipped to ensure that they are replaced in proper position during reassembly.

3. On H233B model, remove the side lock fingers and side bearing caps. Remove side bearings with suitable tools.

4. Remove the differential case from the final drive housing. Mark all parts for correct installation.

5. Attach a flange holding wrench or equivalent to hold flange from turning. Remove the drive pinion nut.

6. Remove the companion flange using suitable puller.

7. Remove the drive pinion together with pinion rear bearing inner cone, drive pinion bearing spacer and pinion bearing adjusting washer.

8. Remove front oil seal and pinion front bearing inner cone.

9. Remove the side oil seals as required.

10. Remove the pinion front and rear bearing outer races with brass drift from housing.

11. Remove the pinion rear bearing inner cone and drive pinion adjusting washer. Remove rear bearing with suitable press and separator plate.

12. Remove side bearing inner race assembly with a puller from the differential carrier. Mark all parts for correct installation.

13. Remove ring gear by spreading out lock straps if so equipped and loosening ring gear bolts in a criss-cross pattern. Remove all retaining bolts.

14. Tap ring gear off gear case using a soft hammer or equivalent. Tap evenly all around to keep ring gear from binding.

15. On C200 and H233B models, separate the left and right differential case halves.

16. On R190A model, drive out pinion mate shaft lock pin with drift pin from ring gear side.

17. Draw out pinion mate shaft and thrust block if so equipped. Rotate pinion mate gears out of case and remove side gears and thrust washers. Put marks on gears and thrust washers so that they can be reinstalled in their original positions from which they were removed.

18. Clean disassembled parts completely. Repair or replace any damaged

or faulty parts. If replacing drive pinion or ring gear, replace with a new hypoid gear as a set.

20. On C200 and H233B models, assemble the differential carrier as follows:

a. Measure the clearance between the side gear thrust washer and differential case.

b. The standard valve for the clearance between side gear thrust washer and differential case is 0.0039–0.0079 in. The clearance can be adjusted with side gear thrust washer.

c. Apply gear oil to gear tooth surfaces and thrust surfaces and check to see they turn properly.

d. Install the left and right differential case halves torque retaining bolts to 40–47 ft. lbs. Position the differential case on the ring gear. Apply Locktite or equivalent and tighten ring gear retaining bolts to (criss-cross fashion) 98–112 ft. lbs. bend up lock straps if so equipped.

e. Press fit side bearings on the differential case using suitable press and tools.

21. On R190A model, assemble the differential carrier as follows:

a. Install pinion mate gears, side gears and thrust washers into differential case.

b. Fit pinion mate shaft and thrust block.

c. Adjust clearance between rear face of side gear and thrust washer by selecting side gear thrust washer.

Exploded view of rear differential assembly—Nissan

The standard valve for clearance on R190A model is 0.0039–0.0079 in. specification.

d. Install pinion mate shaft lock pin using a punch. Make sure lock pin is flush with case.

e. Apply gear oil to gear tooth surfaces and thrust surfaces and check to see they turn properly.

f. Place ring gear on differential case and install new lock straps and bolts. Tighten bolts to 98–112 ft. lbs. in a criss-cross fashion, lightly tapping bolt head with a hammer. Then bend up lock straps to lock the bolts in place.

g. Press fit front and rear bearing outer races using suitable tools. Make sure that the bearing races are seated squarely in their respective bores.

22. Press fit pinion front and rear bearing outer races into housing with suitable tools on all models as necessary.

23. On all models select pinion bearing adjusting washer and drive pinion bearing spacer as follows:

a. Make sure all parts are clean

and that bearings are well lubricate. Assemble the pinion gear bearings into the pinion preload shim selector tool J-34309 or equivalent. Make sure that the front and rear bearings are in the correct position on the special tool (rear bearing first).

b. Install the pinion preload shim selector tool or equivalent into the final drive axle housing. Make sure that the pinion height gauge will make a full turn and tighten the 2 sections by hand. Turn the special tool with bearings installed on it several times to seat the bearings.

c. Measure the turning torque at the end of the tool with a torque wrench. The standard valve for the H190A and C200 models is 8.7–11.3 inch lbs. The standard valve for the R233B model is 3.5–7.8 inch lbs. The standard valve for the R180 model is 7.8–14.8. inch lbs.

d. Place correct pinion height adapter (each model has different pinion height adapter) onto the gauge plate and tighten it by hand.

e. Insert the pinion bearing adjusting spacer squarely into the re-

cessed portion of the correct special tool. Select the correct thickness of the pinion bearing preload adjusting washer using the distance between spacer and gauge anvil tool. The exact measurement you get with the distance between spacer and special tool is the thickness of the adjusting washer required.

f. Position the side bearing discs tool J-25269-4 and arbor firmly in the side bearing bores and torque the side bearing cap bolts to 36–43 ft. lbs. on the H190A model, 65–72 ft. lbs. on the C200 model and 69–76 ft. lbs. on the H233B model.

g. Select the correct standard pinion height adjusting washer thickness using a standard valve plus the distance between pinion height adapter tool and the arbor. The standard valve for the C200 is 0.138 in. The standard valve for the H190A is 0. The standard valve for the H233B is either 0.098, 0.118 or 0.138 in. specification.

h. Correct the pinion height washer size by referring to the pinion head number. There are 2 num-

bers on the pinion gear. The first one refers to the pinion and ring gear as a matched set and the number should be the same on the ring gear. The second number is the pinion head height number and it refers to the ideal pinion height for proper operation. Use this number to determine the correct pinion height washer. Select the correct pinion height washer and remove the special tools with pinion bearings from housing.

24. Install pinion height adjusting washer in drive pinion, bevel side toward gear and press fit rear bearing inner race in it, using press and special tools.

25. Lubricate front bearing with gear oil and place it in gear housing.

26. Carefully fit a new oil seal into carrier. Make sure oil seal is flush with end of carrier and apply multi-purpose grease into cavity between lips.

27. Install the drive pinion bearing spacer, pinion bearing adjusting washer and drive pinion in housing.

28. Install companion flange into drive pinion by tapping with a soft hammer or equivalent.

29. Hold companion flange and temporarily tighten pinion nut, until there is no axial play. Ascertain that threaded portion of drive pinion and pinion nut are free from oil or grease. Tighten pinion nut by degrees to the specified preload while checking the preload with torque wrench. Preload with oil seal is 9.5–13.9 inch lbs. for H190A model and 9.5–14.8 inch lbs. for the C200 model. The preload with oil seal is 4.3–8.7 inch lbs. for H233B model.

30. When checking preload, turn drive pinion in both directions several times set bearing rollers. After preload is reached torque pinion nut to 94–217 ft. lbs. for H190A and C200 models. Torque the pinion nut to 145–181 ft. lbs. on H233B model. Preload and final pinion nut torque must both be attained for correct operation of axle unit.

31. On the H190A model select the side retaining washer as follows:

a. Make sure all parts are cleaned and well lubricated with automatic transmission fluid.

b. Remove the side bearings with suitable tools. Install side bearing old shims on the carrier side away from the ring gear.

c. Reinstall carrier side bearings using suitable press.

d. Install the assembly into the housing. Install side bearing caps and torque retaining bolts to 36–43 ft. lbs.

e. Turn carrier several times to seat bearings. Measure the carrier turning torque with a tool at the

ring gear retaining bolt. The standard valve of pulling force at the ring gear bolt is 7.7–8.8 ft. lbs. Add or subtract shims as necessary. Increase shim thickness to increase turning torque and decrease shim thickness to decrease turning torque. Record correct shim(s) thickness and remove carrier and bearings.

32. On the C200 model select the side retaining washer as follows:

a. Make sure all parts are cleaned and well lubricated with automatic transmission fluid.

b. Install the differential carrier with side bearings and bearing races installed into gear housing.

c. Install side bearing spacer on the ring gear end of the carrier.

d. Install old preload shims using suitable tools on the carrier end opposite the ring gear.

e. Install side bearing caps and torque retaining bolts to 65–72 ft. lbs.

f. Turn carrier several times to seat bearings. Measure the carrier turning torque with a tool at the ring gear retaining bolt. The standard valve of pulling force at the ring gear bolt is 7.7–8.8 ft. lbs. Add or subtract shims as necessary. Record correct shim(s) thickness and remove carrier and bearings.

33. On all models press fit side bearing outer race into side case retainer using suitable tools.

34. On H190A model install differential case assembly with side bearings outer races into housing. On C200 model insert left and right side bearing adjusting washers between side bearing and carrier. Install differential assembly and side bearing spacer using suitable tools.

35. On H233B model install the side bearing adjusters on gear carrier, screw adjusters lightly at this stage.

36. Align mark on bearing caps and install bearing caps torque to 36–43 ft. lbs. on H190A model and 65–72 ft. lbs. on C200 model. On the H223 model do not fully tighten at this point to allow further tightening of side bearing adjusters.

37. On the H190A and C200 models measure the ring gear to drive pinion backlash with a dial indicator. The standard valve is 0.0051–0.0071 in. If backlash is too small, decrease thickness of right shim and increase thickness of left shim by the same amount. If backlash is too great reverse the above procedure. Never change the total amount of shims as it will change the bearing preload.

38. On the H233B model tighten both right and left bearing adjusters alternately and measure the backlash

and total preload at the same time. The standard valve is 0.0059–0.0079 in. Tighten side bearing caps to 69–76 ft. lbs. and install side lock clip in correct position.

39. On the H190A and C200 models check total preload with torque wrench, turn drive pinion several times in both directions to set bearings. The standard valve for total preload is 10–19 inch lbs. for H190A model and 10–20 inch lbs. for the C200 model.

40. On H190 and C200 models if preload is too great, remove the same amount of shims from each side. If preload is too small, add the same amount of shims to each side. Never add or remove a different number of shims for each side as it will change ring gear to drive pinion backlash.

41. Recheck ring gear to drive pinion backlash. Check runout of ring gear the standard valve for runout is 0.0031 in. on all models.

42. Check tooth contact pattern as necessary. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing. On the C200 model install rear cover and gasket.

SUZUKI/GEO

Front and Rear Drive Axles

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Mark side differential side bearing caps for correct installation.

3. Remove the bearing side lock plates and bearing caps. Remove bearing adjusters and outer races. Remove ring gear complete assembly.

4. Remove the flange nut using suitable tools to hold flange.

5. Remove the pinion shaft assembly from the carrier. Remove the pinion shaft oil seal using suitable tools.

6. Remove the outer pinion bearing from the differential carrier.

7. Remove the outer and inner pinion bearing races from the differential carrier.

8. Remove the ring gear bolts and remove the ring gear from the differential assembly.

9. Drive out spring pin (3 spring pins are used on 4 pinion type rear assembly) and remove the differential side gears, selective shims, pinion gears, thrust washers and cross shafts.

Exploded view of rear differential assembly—Suzuki/Geo

25 DRIVE AXLES IMPORT

10. Remove the collapsible spacer and inner pinion bearing using tool and suitable press. Discard the collapsible spacer.

11. Clean disassembled parts completely. Repair or replace any damaged or faulty parts. If replacing drive pinion or ring gear, replace as a set. All taper roller bearings and races must be replaced as a set.

12. Install the differential side gears, thrust washers, cross shaft and side gears with the correct selective shim in the differential case.

13. Measure the differential side gear endplay. The standard value is 0.005–0.14 in. select the correct shim to obtain the standard valve.

14. Drive the spring pin (3 spring pins are used on 4 pinion type rear assembly) for the differential side pinion shaft until it is flush with the case surface.

15. When correct endplay is obtained install the ring gear to differential case. Torque the ring gear (special) retaining bolts to 70 ft. lbs.

16. Install the right and left side differential bearings using suitable tools. Hold one side bearing when installing the other side bearing to prevent damage to any component.

17. Install pinion gear inner bearing race into the differential case using suitable tool and a press.

18. Install pinion gear outer bearing race into the differential case using suitable tool and a press.

19. At this point of the reassembly, set pinion depth. The pinion setting gauge provides in effect a nominal or zero pinion as reference.

20. Lubricate inner and outer pinion bearings with axle lubricant. While holding pinion bearings in the correct position install the pinion depth gauge.

21. Tighten depth gauge stud nut to 18 inch lbs. Rotate the gauge plate several times to seat the bearings. Retighten the locknut on stud of tool to 18 inch lbs.

22. Install special tool side bearing discs and arbor in the correct position in the side bearing bores of the housing.

23. Rotate the gauge plate until the correct area are parallel with the 2 side bearing discs.

24. Position a dial indicator rod over the lower step (94mm) of the gauging plate for front drive axle. Position a dial indicator rod over the higher step (97mm) of the gauging plate for rear drive axle.

25. Connect the dial indicator to the arbor and position gauge shaft over the dial indicator rod.

26. Install the side bearing caps and torque the bolts to 63 ft. lbs.

Contact patterns	Diagnosis and remedy
Outer end Drive side Coast side  Inner end	NORMAL
	HIGH CONTACT Pinion is too far back, therefore, increase bevel pinion adjusting shim.
	LOW CONTACT Pinion is too far out from differential carrier. Decrease bevel pinion adjusting shim.
	Replace differential carrier.
	1. Check seating of bevel gear or differential case. 2. Replace pinion and gear set. 3. Replace differential carrier.
	1. Replace pinion and gear set. 2. Replace differential case.

Differential tooth contact pattern—Suzuki/Geo

27. Position the dial indicator to the zero setting. Slowly rotate the arbor on the lower step (94mm) front drive axle or higher step (97mm) rear driver axle of the gauge plate to determine the point of the greatest defelection. At this point reset the dial indicator to zero setting.

28. Slowly rotate the arbor until the dial indicator is no longer on the gauge plate.

29. Record the dial indicator reading. This reading indicates the selective shim required for the correct pinion depth. The selective shims range from 0.012–0.050 in.

30. Install the correct pinion shim on the pinion gear shaft.

31. Assemble the inner pinion bearing on the pinion gear shaft using suitable press plate and press.

32. Install new collapsible spacer on the pinion gear shaft.

33. Install the outer pinion bearing in the differential carrier using suitable tools.

34. Apply lubricant to the oil seal lip. Install the new pinion oil seal using a suitable seal installer or equivalent.

35. Install pinion flange, pinion washer and nut. Hold the pinion flange (suitable flange holding tool) while frequently rotating pinion to seal pinion bearings. Tighten pinion flange nut (little at a time) until endplay is taken up. Measure preload with torque wrench the standard valve for all applications is 11 inch lbs. of starting torque not rotating torque. Exceeding preload specification will compress the collapsible spacer.

36. After final preload has been reached rotate the pinion several times to make sure the bearings have been seated. Recheck the preload specification.

37. Install the ring gear and differential carrier assembly, side bearing outer races, bearing adjusters and bearing caps to housing. Align all identification marks.

38. Rotate pinion gear to ensure the

side bearings seat. Tighten bearing caps 15 ft. lbs. on the front and rear drive axle assembly.

39. Using suitable tool turn the bearing adjusters to push side bearings lightly from outside so that outer races are in contact with inner races. Apply a small amount of lubricant to bearings. With dial indicator installed to differential carrier and carrier at 0.0 backlash (ring gear fully engaged into pinion gear) set or check preload. The differential side bearing preload is 0.002–0.006 in.

40. Rotate pinion gear to ensure the side bearings seat. Tighten bearing caps to 44 ft. lbs. on the front drive axle assembly and 63 ft. lbs. on the rear drive axle assembly.

41. Check backlash using a dial indicator installed to the differential ring gear. The standard valve for all applications is 0.008–0.015 in. If adjustment is necessary loosen one adjuster nut and tighten the opposite nut an equal amount. This will move the ring

gear away from or toward the pinion gear and maintain side bearing preload.

42. When turning the side bearing adjusters the final movement must be made in the tightening direction to ensure correct side bearing preload.

43. Install the side bearing lock plates. Torque the side bearing lock plate bolts to 25 ft. lbs.

44. Paint the ring gear with suitable marking compound and rotate the pinion flange to obtain a tooth mesh contact pattern.

45. Inspect pattern contact and adjust or service the assembly as required. After all adjustments and correct pattern contact is obtained stake the pinion flange locknut.

46. Apply gear oil to all moving parts and use sealant and or gasket when assembling to the axle housing.

TOYOTA

Front and Rear Drive Axles

Disassembly and Assembly

1. Position the removed differential carrier assembly in a suitable holding fixture.

2. Measure the side gear backlash while holding one pinion gear toward the case. The standard valve is 0.0020–0.0079 in. on all except Land Cruiser. The standard valve for Land Cruiser is 0.0008–0.0079 in.

3. Check ring gear runout. Maximum runout is 0.0028 in. on all except Land Cruiser. The standard valve for Land Cruiser is 0.0039 in.

NOTE: On rear axle assembly with 7½ in. ring gear the runout is 0.0028. On rear axle assembly with 8 in. ring gear the runout is 0.0039 in.

4. Hold drive pinion flange check ring gear backlash (several different locations). The standard valve is 0.0051–0.0071 in. on all except Land Cruiser. The standard valve for Land Cruiser is 0.0059–0.0079 in.

5. Inspect tooth contact between ring gear and drive pinion using suitable marking compound.

6. Using a torque wrench measure the (starting) preload of the backlash between the drive pinion and ring gear. The standard valve is 5.2–8.7 inch lbs. for all vehicles except Land Cruiser and vans. The standard valve specification for Land Cruiser is 6.1–

8.7 inch lbs. and 4.3–6.9 inch lbs. for vans.

NOTE: On rear axle assembly with 7½ in. ring gear the drive pinion preload is 5.2–8.7 inch lbs. On rear axle assembly with 8 in. ring gear 2 pinion type the drive pinion preload is 7.8–11.3 inch lbs. and 4.3–6.9 inch lbs. on 4 pinion type.

7. The total preload specification standard valve is 1.6–3.0 inch lbs. for all vehicles except Land Cruiser and vans. The standard valve specification for Land Cruiser is 3.5–5.2 inch lbs. and 2.6–4.3 inch lbs. for vans. This measurement is total preload (starting) also adding drive pinion preload to the specification.

8. Loosen the the staked part of the flange retaining nut. Remove the nut using a suitable tool to hold flange. Remove flange using a puller or equivalent.

9. Remove the companion flange oil seal and slinger from the housing.

10. Remove the rear bearing spacer and rear bearing from the drive pinion.

11. Put alignment marks on the bearing cap and differential carrier.

12. Remove both bearing caps. Remove both side bearing preload adjusting washers.

13. Remove the differential case with bearing outer races (mark for correct installation) from the carrier.

14. Remove the drive pinion from the differential carrier.

15. Remove the front bearing from the drive pinion using a suitable tool and press.

16. Remove the drive pinion front and rear bearing outer races from the housing.

17. Remove the side bearing from the differential case using suitable puller. Puller jaws must align with notches in the differential case.

18. Remove the ring gear retaining bolts and lock plates.

19. Place matchmarks on the ring gear then using a plastic tool or equivalent separate it from the differential case.

20. Drive out the straight pin and remove the pinion shaft, pinion gears, side gears and thrust washers.

21. Assemble the differential case by installing the correct (check backlash with dial indicator) thrust washer to side gears. Try to select washers of the same thickness for both sides. Install the thrust washer and side gears in the differential case.

NOTE: On some rear axle assemblies the differential case splits. The retaining torque for

left and right case halves is 35 ft. lbs.

22. Temporarily install the side gear shaft. Measure the side gear backlash the standard valve is 0.0020–0.0079 in. on all vehicles except Land Cruiser. The standard valve for Land Cruiser is 0.0008–0.0079 in.

23. Drive the straight pin through the case and hole in the pinion shaft. Stake the pin and differential case.

24. Clean the contact surface of the differential case before installing the ring gear to the assembly.

25. Heat the ring gear in oil bath to about 212 degrees Fahrenheit then quickly install the ring gear on the differential case. Caution should be used when performing this service operation.

26. Align the matchmarks on the ring gear differential case. Coat the ring gear bolts with gear oil install the lock plates and retaining bolts.

27. After the ring gear cools down enough, torque the retaining bolts uniformly and little at a time. The standard valve torque for ring gear installation is 71 ft. lbs. on all trucks and vans except Land Cruiser. The standard valve for Land Cruiser is 81 ft. lbs. Stake the lock plates on all applications.

28. Using a suitable press plate and press install the side bearings into the differential case.

29. Install the differential case onto the carrier assembly. Install the plate washers where there is no play in the bearings.

30. Install the bearing caps using a dial indicator measure the runout of the ring gear. The standard valve for runout is 0.0028 in. on all except Land Cruiser. The standard valve for Land Cruiser is 0.0039 in. after runout inspection is performed remove the assembly from the carrier.

NOTE: On rear axle assembly with 7½ in. ring gear the runout is 0.0028. On rear axle assembly with 8 in. ring gear the runout is 0.0039 in.

31. Install the front and rear pinion bearing outer races to the carrier.

32. Install the drive pinion assembly (rear bearing) and front bearing in housing. Install the companion flange with a suitable tool to hold flange in place.

33. Rotate the flange several times to seat the bearing. Adjust the drive pinion preload by tightening the flange nut. Use a torque wrench to measure the preload. The standard valve for preload (starting torque) is 10.4–16.5 inch lbs. on trucks. The standard valve for preload (starting torque) is 8.7–13.9 inch lbs. on vans. The standard

Exploded view of front differential assembly—Toyota

valve for preload (starting torque) specification is 11.3–17.4 inch lbs. on Land Crusier. In order to measure the total preload, record this preload specification.

NOTE: On rear axle assembly with 7½ in. ring gear the preload (starting torque) is 10.4–16.5 inch lbs. On rear axle assembly with 8 in. ring gear 2 pinion type the preload (starting torque) specification is 16.5–22.6 inch lbs. and 8.7–13.9 inch lbs. on 4 pinion type.

34. Install the bearing outer races in the correct location. Install the differential case in the carrier.

35. At this point of reassembly, on all front drive axle vehicles except Land Crusier use the following procedure:

a. Insure the ring gear has backlash. Install only the plate washer on the ring gear back side.

b. Snug down on the washer and bearing by pushing the ring gear into the housing.

c. Hold the side bearing boss on the teeth surface of the ring gear and measure the backlash. The standard valve for backlash is 0.0051 in. Select a ring gear plate washers as required.

d. Install both (as required) the adjusting washers and differential case into the carrier.

e. Using a dial indicator, measure the ring gear backlash again to obtain the standard valve. Adjust by either increasing or decreasing the

number of washers on both sides by a equal amount. Insure that ring gear has standard valve of backlash.

36. Adjust the side bearing preload by removing the ring gear adjusting washer and measure the thickness. Using the backlash as a reference specification select a correct washer to obtain the standard valve of backlash (0.0051–0.0071 in.) by increasing or decreasing the washer thickness on both sides by an equal amount.

37. Install the side bearing caps in the correct position. Torque the side bearing cap bolts to 58 ft. lbs.

38. Measure the total preload using a torque wrench. The total preload specification standard valve is 1.6–3.0 inch lbs. for all trucks except for trucks with automatic disconnecting differential assembly which is 3.5–5.2 inch lbs. The standard valve specification for vans 2.6–4.3 inch lbs. This measurement is total preload (starting) also add drive pinion preload to the specification.

39. At this point of reassembly, on rear drive axle vehicles and Land Crusier use the following procedure:

a. Install the adjusting nuts in the correct location in the carrier.

b. Align the marks on the cap and carrier. Insure that bearing caps and adjusting nuts are installed properly.

c. Torque the bearing caps bolts until the spring washers are slightly compressed.

d. Tighten the adjusting nuts (equal amount on both sides) on the

ring gear side until the ring gear backlash is 0.0051–0.0071 in. for all trucks and vans rear axle assemblies and 0.0059–0.0079 in. on Land Crusier.

40. Install the side bearing caps in the correct position. Torque the side bearing cap bolts to 58 ft. lbs.

41. Recheck the ring gear backlash standard valve specification.

42. Measure the total preload using a torque wrench. The total preload specification standard valve is 3.5–5.2 inch lbs. This measurement is total preload (starting) also add drive pinion preload to the specification.

43. On all applications inspect tooth pattern contact between ring gear and drive pinion. Adjust as required.

44. Remove the companion flange and drive pinion bearing. Install new bearing spacer on the drive pinion. Install the bearing.

45. Install oil slinger and new oil seal. The oil seal drive in depth is 0.059 in. for trucks, 0.0079 in. for vans and 0.0039 in. for Land Crusier.

NOTE: On rear axle assembly with 7½ in. ring gear the oil seal drive depth is 0.059 in. On rear axle assembly with 8 in. ring gear the oil seal drive depth is 0.039 in. specification.

46. Using suitable tools install the companion flange. Coat the threads of the new nut with lubricant or equivalent.

47. The torque specification for the companion flange is 89 ft. lbs. on

Proper Contact

Heel Contact

Face Contact

Select an adjusting shim that will bring the drive pinion closer to the ring gear.

Toe Contact

Flank Contact

Select an adjusting shim that will shift the drive pinion away from the ring gear.

Differential tooth contact pattern—Toyota

kg-cm (ft-lb, N-m) : Specified torque

◆ Non-reusable part

Exploded view of rear differential assembly—Toyota

trucks, 80 ft. lbs. on vans and 181 ft. lbs on Land Cruiser.

NOTE: On rear axle assembly with 7½ in. ring gear the flange torque is 80 ft. lbs. On rear axle assembly with 8 in. ring gear the flange torque is 145 ft. lbs.

48. Check drive pinion bearing preload. The standard value for preload (starting torque) is 10.4–16.5 inch lbs. on trucks. The standard value for preload (starting torque) is 8.7–13.9 inch lbs. on vans. The standard value for preload (starting torque) specification is 11.3–17.4 inch lbs. on Land Crusier.

NOTE: On rear axle assembly with 7½ in. ring gear the preload (starting torque) is 10.4–16.5 inch lbs. On rear axle assembly with 8

in. ring gear 2 pinion type the preload (starting torque) specification is 16.5–22.6 inch lbs. and 8.7–13.9 inch lbs. on 4 pinion type.

49. If the preload is greater than specification, replace the bearing spacer. If the preload is less than specification, retighten flange nut (little at a time) until preload is reached.

50. The maximum torque on the new companion flange nut is 165 ft. lbs. on trucks, 174 ft. lbs. on vans and 325 ft. lbs on Land Cruiser.

NOTE: On rear axle assembly with 7½ in. ring gear the maximum torque on the new companion flange nut is 174 ft. lbs. On rear axle assembly with 8 in. ring gear the maximum torque is 253 ft. lbs.

51. Recheck total preload and ring gear backlash as necessary. Inspect tooth contact pattern between ring gear and drive pinion.

52. Using a dial indicator measure the runout (vertical and lateral) of companion flange, maximum runout is 0.0039 in. Stake drive pinion nut.

53. On all front drive axle vehicles except Land Cruiser, install a attaching components to axle housing. Install rear cover with suitable sealant or gasket torque retaining bolts to 34 ft. lbs.

54. On rear drive axle vehicles and Land Cruiser vehicles select correct locks, whichever will fit the adjusting nuts. Torque the lock retaining bolts to 9 ft. lbs.

Troubleshooting 26

ENGINE

Gasoline Engine Troubleshooting

See applicable Car or Unit Repair section for specific service procedures

INDEX TO PROBLEMS

Problem Symptom	Begin at Specific Diagnosis, Number
Engine Won't Start	
Starter doesn't turn	1.1, 2.1
Starter turns, engine doesn't	2.1
Starter turns engine very slowly	1.1, 2.4
Starter turns engine normally	3.1, 4.1
Starter turns engine very quickly	6.1
Engine fires intermittently	4.1
Engine fires consistently	5.1, 6.1
Engine Runs Poorly	
Hard starting	3.1, 4.1, 5.1, 8.1
Rough idle	4.1, 5.1, 8.1
Stalling	3.1, 4.1, 5.1, 8.1
Engine dies at high speeds	4.1, 5.1
Hesitation (on acceleration from standing stop)	5.1, 8.1
Poor pickup	4.1, 5.1, 8.1
Lack of power	3.1, 4.1, 5.1, 8.1
Backfire through the carburetor	4.1, 8.1, 9.1
Backfire through the exhaust	4.1, 8.1, 9.1
Blue exhaust gases	6.1, 7.1
Black exhaust gases	5.1
Running on (after the ignition is shut off)	3.1, 8.1
Susceptible to moisture	4.1
Engine misfires under load	4.1, 7.1, 8.4, 9.1
Engine misfires at speed	4.1, 8.4
Engine misfires at idle	3.1, 4.1, 5.1, 7.1, 8.4

SAMPLE SECTION

Test and Procedure	Results and Indications	Proceed to
4.1 Check for spark: Hold each spark plug wire approximately 1/4" from ground with gloves or a heavy, dry rag. Crank the engine and observe the spark.	If no spark is evident If spark is good in some cases If spark is good in all cases	4.2 4.3 4.6

SPECIFIC DIAGNOSIS

This section is arranged so that following each test, instructions are given to proceed to another, until a problem is diagnosed.

SECTION 1—BATTERY

Test and Procedure	Results and Indications	Proceed to
1.1 Inspect the battery visually for case condition (corrosion, cracks) and water level. DIRT ON TOP OF BATTERY CORROSION PLUGGED VENT LOOSE CABLE OR POSTS CRACKS LOW WATER LEVEL Inspect the battery case	If case is cracked, replace battery. If the case is intact, remove corrosion with a solution of baking soda and water. (CAUTION: Do not get the solution into the battery). Fill with water.	1.4 1.2
1.2 Check the battery cable connections: Insert a screwdriver between the battery post and the cable clamp. Turn the headlights on high beam, and observe them as the screwdriver is gently twisted to ensure good metal to metal contact. TESTING BATTERY CABLE CONNECTIONS USING A SCREWDRIVER	If the lights brighten, remove and clean the clamp and post; coat the post with petroleum jelly, install and tighten the clamp. If no improvement is noted	1.4 1.3

1.3 Test the state of charge of the battery using an individual cell tester or hydrometer.

The diagram shows a hydrometer with two vertical scales. The left scale is for temperature in degrees Fahrenheit (°F), ranging from -100 to 80. The right scale is for specific gravity, ranging from 1.10 to 1.32. Two arrows point to the right scale with the following instructions:

- ADD THIS NUMBER TO THE HYDROMETER READING TO OBTAIN THE CORRECTED SPECIFIC GRAVITY
- SUBTRACT THIS NUMBER FROM THE HYDROMETER READING TO OBTAIN THE CORRECTED SPECIFIC GRAVITY

If indicated, charge the battery.

1.4

NOTE: If no obvious reason exists for the low state of charge (i.e., battery age, prolonged storage), proceed to:

Specific Gravity (@ 80° F.)

Minimum	Battery Charge
1.260	100% Charged
1.230	75% Charged
1.200	50% Charged
1.170	25% Charged
1.140	Very Little Power Left
1.110	Completely Discharged

The effects of temperature on battery specific gravity (left) and amount of battery charge in relation to specific gravity (right)

Test and Procedure	Results and Indications	Proceed To
1.4 Visually inspect battery cables for cracking, bad connection to ground, or bad connection to starter.	If necessary, tighten connections or replace the cables.	2.1

SECTION 2—STARTING SYSTEM

Test and Procedure	Results and Indications	Proceed to
Note: Tests in Group 2 are performed with coil high tension lead disconnected to prevent accidental starting.		
2.1 Test the starter motor and solenoid: Connect a jumper from the battery post of the solenoid (or relay) to the starter post of the solenoid (or relay).	If starter turns the engine normally If the starter buzzes, or turns the engine very slowly If no response, replace the solenoid (or relay). If the starter turns, but the engine doesn't, ensure that the flywheel ring gear is intact. If the gear is undamaged, replace the starter drive.	2.2 2.4 3.1 3.1
2.2 Determine whether ignition override switches are functioning properly (clutch start switch, neutral safety switch), by connecting a jumper across the switch(es), and turning the ignition switch to "start".	If starter operates, adjust or replace switch. If the starter doesn't operate	3.1 2.3
2.3 Check the ignition switch "start" position: Connect a 12V test lamp or voltmeter between the starter post of the solenoid (or relay) and ground. Turn the ignition switch to the "start" position, and jiggle the key.	If the lamp doesn't light or the meter needle doesn't move when the switch is turned, check the ignition switch for loose connections, cracked insulation, or broken wires. Repair or replace as necessary. If the lamp flickers or needle moves when the key is jiggled, replace the ignition switch.	3.1 3.3

Checking the ignition switch "start" position

2.4 Remove and bench test the starter, according to specifications in the car section.	If the starter does not meet specifications, repair or replace as needed If the starter is operating properly	3.1 2.5
--	--	------------

26 TROUBLESHOOTING

Test and Procedure	Results and Indications	Proceed To
2.5 Determine whether the engine can turn freely: Remove the spark plugs, and check for water in the cylinders. Check for water on the dipstick, or oil in the radiator. Attempt to turn the engine using an 18" flex drive and socket on the crankshaft pulley nut or bolt.	If the engine will turn freely only with the spark plugs out, and hydrostatic lock (water in the cylinders) is ruled out, check valve timing. If engine will not turn freely, and it is known that the clutch and transmission are free, the engine must be disassembled for further evaluation.	9.2 See Car Section

SECTION 3—PRIMARY ELECTRICAL SYSTEM

Test and Procedure	Results and Indications	Proceed to
3.1 Check the ignition switch "on" position: Connect a jumper wire between the distributor side of the coil and ground, and a 12V test lamp between the switch side of the coil and ground. Remove the high tension lead from the coil. Turn the ignition switch on and jiggle the key.	If the lamp lights If the lamp flickers when the key is jiggled, replace the ignition switch. If the lamp doesn't light, check for loose or open connections. If none are found, remove the ignition switch and check for continuity. If the switch is faulty, replace it.	3.2 3.3 3.3
 Checking the ignition switch "on" position		
3.2 Check the ballast resistor or resistance wire for an open circuit, using an ohmmeter.	Replace the resistor or resistance wire if the resistance is zero. NOTE: Some ignition systems have no ballast resistor.	3.3
 Two types of resistors		
3.3 On point-type ignition systems, visually inspect the breaker points for burning, pitting or excessive wear. Gray coloring of the point contact surfaces is normal. Rotate the crankshaft until the contact heel rests on a high point of the distributor cam and adjust the point gap to specifications. On electronic ignition models, remove the distributor cap and visually inspect the armature. Ensure that the armature pin is in place, and that the armature is on tight and rotates when the engine is cranked. Make sure there are no cracks, chips or rounded edges on the armature.	If the breaker points are intact, clean the contact surfaces with fine emery cloth, and adjust the point gap to specifications. If the points are worn, replace them. On electronic systems, replace any parts which appear defective. If condition persists	3.4

Test and Procedure	Results and Indications	Proceed To
3.4 On point-type ignition systems, connect a dwell-meter between the distributor primary lead and ground. Crank the engine and observe the point dwell angle. On electronic ignition systems, conduct a stator (magnetic pickup assembly) test. See Electronic Ignition Unit Repair Section.	On point-type systems, adjust the dwell angle if necessary. NOTE: Increasing the point gap decreases the dwell angle and vice-versa. If the dwell meter shows little or no reading On electronic ignition systems, if the stator is bad, replace the stator. If the stator is good, proceed to the other tests in The Electronic Ignition Unit Repair Section.	3.6 3.5

Dwell is a function of point gap

3.5 On the point-type ignition systems, check the condenser for short: connect an ohmmeter across the condenser body and the pigtail lead.	If any reading other than infinite is noted, replace the condenser	3.6
---	---	------------

Checking the condenser for short

3.6 Test the coil primary resistance: On point-type ignition systems, connect an ohmmeter across the coil primary terminals, and read the resistance on the low scale. Note whether an external ballast resistor or resistance wire is used. On electronic ignition systems, test the coil primary resistance.	Point-type ignition coils utilizing ballast resistors or resistance wires should have approximately 1.0 ohms resistance. Coils with internal resistors should have approximately 4.0 ohms resistance. If values far from the above are noted, replace the coil.	4.1
---	--	------------

Checking the coil primary resistance

SECTION 4—SECONDARY ELECTRICAL SYSTEM

Test and Procedure	Results and Indications	Proceed to
4.1 Check for spark: Hold each spark plug wire approximately 1/4" from ground with gloves or heavy, dry rag. Crank the engine, and observe the spark.	If no spark is evident If spark is good in some cylinders If spark is good in all cylinders	4.2 4.3 4.6
 Check for spark at the plugs		
4.2 Check for spark at the coil high tension lead: Remove the coil high tension lead from the distributor and position it approximately 1/4" from ground. Crank the engine and observe spark. CAUTION: This test should not be performed on engines equipped with electronic ignition.	If the spark is good and consistent If the spark is good but intermittent, test the primary electrical system starting at 3.3. If the spark is weak or non-existent, replace the coil high tension lead, clean and tighten all connections and retest. If no improvement is noted	4.3 3.3 4.4
4.3 Visually inspect the distributor cap and rotor for burned or corroded contacts, cracks, carbon tracks, or moisture. Also check the fit of the rotor on the distributor shaft (where applicable).	If moisture is present, dry thoroughly, and retest per 4.1. If burned or excessively corroded contacts, cracks, or carbon tracks are noted, replace the defective part(s) and retest per 4.1. If the rotor and cap appear intact, or are only slightly corroded, clean the contacts thoroughly (including the cap towers and spark plug wire ends) and retest per 4.1. If the spark is good in all cases If the spark is poor in all cases	4.1 4.1 4.6 4.5
 Inspect the distributor cap and rotor		
4.4 Check the coil secondary resistance: On point-type systems connect an ohmmeter across the distributor side of the coil and the coil tower. Read the resistance on the high scale of the ohmmeter. On electronic ignition systems, see The Electronic Ignition Unit Repair Section for specific tests.	The resistance of a satisfactory coil should be between 4,000 and 10,000 ohms. If resistance is considerably higher (i.e., 40,000 ohms) replace the coil and retest per 4.1. NOTE: This does not apply to high performance coils.	
 Testing the coil secondary resistance		

Spark Plug Analysis

Normal

APPEARANCE

This plug is typical of one operating normally. The insulator nose varies from a light tan to grayish color with slight electrode wear. The presence of slight deposits is normal on used plugs and will have no adverse effect on engine performance. The spark plug heat range is correct for the engine and the engine is running normally.

CAUSE

Properly running engine

RECOMMENDATION

Before reinstalling this plug, the electrodes should be cleaned and filed square. Set the gap to specifications. If the plug has been in service for more than 10–12,000 miles, the entire set should probably be replaced with a fresh set of the same heat range.

Incorrect Heat Range

APPEARANCE

The effects of high temperature on a spark plug are indicated by clean white, often blistered insulator. This can also be accompanied by excessive wear of the electrode, and the absence of deposits.

CAUSE

Check for the correct spark plug heat range. A plug which is too hot for the engine can result in overheating. A car operated mostly at high speeds may require a colder plug. Also check ignition timing, cooling system level, fuel mixture and leaking intake manifold.

RECOMMENDATION

If all ignition and engine adjustments are known to be correct, and no other malfunction exists, install spark plugs one heat range colder.

Oil Deposits

APPEARANCE

The firing end of the plug is covered with a wet, oily coating.

CAUSE

The problem is poor oil control. On high mileage engines, oil is leaking past the rings or valve guides into the combustion chamber. A common cause is also a plugged PCV valve, and a ruptured fuel pump diaphragm can also cause this condition. Oil fouled plugs such as these are often found in new or recently overhauled engines, before normal oil control is achieved, and can be cleaned and reinstalled.

RECOMMENDATION

A hotter spark plug may temporarily relieve the problem, but the engine is probably in need of engine work.

Carbon Deposits

APPEARANCE

Carbon fouling is easily identified by the presence of dry, soft, black, sooty deposits.

CAUSE

Changing the heat range can often lead to carbon fouling, as can prolonged slow, stop-and-start driving. If the heat range is correct, carbon fouling can be attributed to a rich fuel mixture, sticking choke, clogged air cleaner, worn breaker points, retarded timing or low compression. If only one or two plugs are carbon fouled, check for corroded or cracked wires on the affected plugs. Also look for cracks in the distributor cap between the towers of affected cylinders.

RECOMMENDATION

After the problem is corrected, these plugs can be cleaned and reinstalled if not worn severely.

Ash Deposits

APPEARANCE

Ash deposits are characterized by light brown or white colored deposits crusted on the side or center electrodes. In some cases it may give the plug a rusty appearance.

CAUSE

Ash deposits are normally derived from oil or fuel additives burned during normal combustion. Normally they are harmless, though excessive amounts can cause misfiring. If deposits are excessive in short mileage, the valve guides may be worn. Reddish or rusty deposits are caused by manganese, an anti-knock compound replacing lead in unleaded gas. No engine malfunction is indicated.

RECOMMENDATION

Ash-fouled plugs can be cleaned, gapped and reinstalled.

Splash Deposits

APPEARANCE

Splash deposits occur in varying degrees as spotty deposits on the insulator.

CAUSE

These usually occur after a long delayed tune-up. By-products of combustion have accumulated on pistons and valves because of a delayed tune-up. Following tune-up or during hard acceleration, the deposits loosen and are thrown against the hot surface of the plug. If the deposits accumulate sufficiently, misfiring can occur.

RECOMMENDATION

These plugs can be cleaned, gapped and reinstalled.

High Speed Glazing

APPEARANCE

Glazing appears as shiny coating on the plug, either yellow or tan in color.

CAUSE

During hard, fast acceleration, plug temperatures rise suddenly. Deposits from normal combustion have no chance to fluff-off; instead, they melt on the insulator forming an electrically conductive coating which causes misfiring.

RECOMMENDATION

Glazed plugs are not easily cleaned. They should be replaced with a fresh set of plugs of the correct heat range. If the condition recurs, using plugs with a heat range one step colder may cure the problem.

Detonation

APPEARANCE

Detonation is usually characterized by a broken plug insulator.

CAUSE

A portion of the fuel charge will begin to burn spontaneously, from the increased heat following ignition. The explosion that results applies extreme pressure to engine components, frequently damaging spark plugs and pistons.

Detonation can result by over-advanced ignition timing, inferior gasoline (low octane) lean air fuel mixture, poor carburetion, engine lugging or an increase in compression ratio due to combustion chamber deposits or engine modification.

RECOMMENDATION

Replace the plugs after correcting the problem.

Test and Procedure	Results and Indications	Proceed To
--------------------	-------------------------	------------

4.5 Visually inspect the spark plug wires for cracking or brittleness. Ensure that no two wires are positioned so as to cause induction firing (adjacent and parallel). Remove each wire, one by one, and check resistance with an ohmmeter.

Misfiring can be the result of spark plug leads to adjacent, consecutively firing cylinders running parallel and too close together

On point-type ignition systems, check the spark plug wires as shown. On electronic ignitions, do not remove the wire from the distributor cap terminal; instead, test through the cap

Spark plugs wires can be checked visually by bending them in a loop over your finger. This will reveal any cracks, burned or broken insulation. Any wire with cracked insulation should be replaced

Replace any cracked or brittle wires. If any of the wires are defective, replace the entire set. Replace any wires with excessive resistance (over 8000 Ω per foot for suppression wire), and separate any wires that might cause induction firing.

4.6

4.6 Remove the spark plugs, noting the cylinders from which they were removed, and evaluate according to the chart in this section.

See chart.

See Chart

4.7 Reinstall the spark plugs.
NOTE: Modern electronic ignition systems generate extremely high voltages and high heats. The spark plug boots can soften and actually fuse to the ceramic insulator of the spark plugs after long exposures to high temperature and voltage. If this happens, the boot (and possibly the wire) must be replaced.

To help alleviate this condition, many manufacturers are recommending new silicone compounds to slow the deterioration. The compounds are generally nonconductive, protective lubricants that will not dry out, harden, or melt away. They form a weather-tight seal between rubber or plastic and metal and are found in several typical locations: Inside the insulating boots of spark plug wires, inside primary ignition circuit cable connectors, on distributor and rotor cap electrodes, and under the GM HEI control module.

4.8

Application Point	Silicone Compound
GENERAL MOTORS: Under HEI module	Supplied with new module, or use GE-642 or DC-340
FORD MOTOR COMPANY: Inside spark plug boots, on end of cable when installing new boot, and on rotor and cap electrodes	Ford part number D7AZ-19A331-A or use GE-627 or DC-111
CHRYSLER CORPORATION: 1/4" deep within spark control computer connector cavity coating rotor electrode	Use Mopar part number 2932524 or NLGI Grade 2 EP (not a silicone) supplied with new rotor, or use GE-628 or DC-111
AMERICAN MOTORS (Prestolite system): Distributor primary connector—coat male terminal, fill female 1/4 full	AMC part number 8127445 or GE-623

GE: General Electric
DC: Dow Corning

Test and Procedure	Results and Indications	Proceed To
4.8 Examine the location of all the plugs.  Two adjacent plugs are fouled in a 6-cylinder engine, 4-cylinder engine or either bank of a V-8. This is probably due to a blown head gasket between the two cylinders.  An unbalanced carburetor is indicated. Following the fuel flow on this particular design shows that the cylinders fed by the right-hand barrel are fouled from overly rich mixture, while the cylinders fed by the left-hand barrel are normal.  Finding one plug overheated may indicate an intake manifold leak near the affected cylinder. If the overheated plug is the second of two adjacent, consecutively firing plugs, it could be the result of ignition cross-firing. Separating the leads to these two plugs will eliminate cross-fire.	The following diagrams illustrate some of the conditions that the location of plugs will reveal.  The two center plugs in a 6-cylinder engine are fouled. Raw fuel may be "boiled" out of the carburetor into the intake manifold after the engine is shut-off. Stop-start driving can also foul the center plugs, due to overly rich mixture. Proper float level, a new float needle and seat or use of an insulating spacer may help this problem.  If the four rear plugs are overheated, a cooling system problem is suggested. A thorough cleaning of the cooling system may restore coolant circulation and cure the problem.  Occasionally, the two rear plugs in large, lightly used V-8's will become oil fouled. High oil consumption and smoky exhaust may also be noticed. It is probably due to plugged oil drain holes in the rear of the cylinder head, causing oil to be sucked in around the valve stems. This usually occurs in the rear cylinders first, because the engine slants that way.	4.9

Test and Procedure	Results and Indications	Proceed To
4.9 Determine the static ignition timing. Using the crankshaft pulley timing marks as a guide, locate top dead center on the compression stroke of the number one cylinder.	The rotor should be pointing toward the No. 1 tower in the distributor cap, and, on electronic ignitions, the armature spoke for that cylinder should be lined up with the stator.	4.10
4.10 Check coil polarity: Connect a voltmeter negative lead to the coil high tension lead, and the positive lead to ground. NOTE: Reverse the hook-up for positive ground systems. Crank the engine momentarily.	 If the voltmeter reads up-scale, the polarity is correct. If the voltmeter reads down-scale, reverse the coil polarity (switch the primary leads).	5.1 5.1

Checking coil polarity

SECTION 5—FUEL SYSTEM

Test and Procedure	Results and Indications	Proceed to
5.1 Determine that the air filter is functioning efficiently: Hold paper elements up to a strong light, and attempt to see light through the filter.	Clean permanent air filters in solvent (or manufacturer's recommendation), and allow to dry. Replace paper elements through which light cannot be seen.	5.2
5.2 Determine whether a flooding condition exists: Flooding is identified by a strong gasoline odor, and excessive gasoline present in the throttle bore(s) of the carburetor.	If flooding is not evident If flooding is evident, permit the gasoline to dry for a few moments and restart. If flooding doesn't recur If flooding is persistent	5.3 5.7 5.5
5.3 Check that fuel is reaching the carburetor: Detach the fuel line at the carburetor inlet. Hold the end of the line in a cup (not styrofoam), and crank the engine.	If fuel flows smoothly If fuel doesn't flow If fuel flows erratically. NOTE: Make sure that there is fuel in the tank	5.7 5.4

If the engine floods repeatedly, check the choke butterfly flap

Check the fuel pump by disconnecting the output line (fuel pump-to-carburetor) at the carburetor and operating the starter briefly

26 TROUBLESHOOTING

Test and Procedure	Results and Indications	Proceed To
5.4 Test the fuel pump: Disconnect all fuel lines from the fuel pump. Hold a finger over the input fitting, crank the engine (with electric pump, turn the ignition or pump on); and feel for suction.	If suction is evident, blow out the fuel line to the tank with low pressure compressed air until bubbling is heard from the fuel filler neck. Also blow out the carburetor fuel line (both ends disconnected). If no suction is evident, replace or repair the fuel pump. NOTE: Repeated oil fouling of the spark plugs, or a no-start condition, could be the result of a ruptured vacuum booster pump diaphragm, through which oil or gasoline is being drawn into the intake manifold (where applicable).	5.7 5.7
5.5 Occasionally, small specks of dirt will clog the small jets and orifices in the carburetor. With the engine cold, hold a flat piece of wood or similar material over the carburetor, where possible, and crank the engine.	If the engine starts, but runs roughly the engine is probably not run enough. If the engine won't start.	5.9
5.6 Check the needle and seat: Tap the carburetor in the area of the needle and seat.	If flooding stops, a gasoline additive (e.g., Gumout) will often cure the problem. If flooding continues, check the fuel pump for excessive pressure at the carburetor (according to specifications). If the pressure is normal, the needle and seat must be removed and checked, and/or the float level adjusted.	5.7 5.7
5.7 Test the accelerator pump by looking into the throttle bores while operating the throttle.	If the accelerator pump appears to be operating normally If the accelerator pump is not operating, the pump must be reconditioned. Where possible, service the pump with the carburetor(s) installed on the engine. If necessary, remove the carburetor. Prior to removal	5.8 5.8
Check for gas at the carburetor by looking down the carburetor throat while someone moves the accelerator		
5.8 Determine whether the carburetor main fuel system is functioning: Spray a commercial starting fluid into the carburetor while attempting to start the engine.	If the engine starts, runs for a few seconds, and dies If the engine doesn't start	5.9 6.1
5.9 Uncommon fuel system malfunctions: See below:	If the problem is solved If the problem remains, remove and recondition the carburetor.	6.1

Condition	Indication	Test	Prevailing Weather Conditions	Remedy
Vapor lock	Engine will not re-start shortly after running.	Cool the components of the fuel system until the engine starts. Vapor lock can be cured faster by draping a wet cloth over a mechanical fuel pump.	Hot to very hot	Ensure that the exhaust manifold heat control valve is operating. Check with the vehicle manufacturer for the recommended solution to vapor lock on the model in question.
Carburetor icing	Engine will not idle, stalls at low speeds.	Visually inspect the throttle plate area of the throttle bores for frost.	High humidity, 32–40° F.	Ensure that the exhaust manifold heat control valve is operating, and that the intake manifold heat riser is not blocked.
Water in the fuel	Engine sputters and stalls; may not start.	Pump a small amount of fuel into a glass jar. Allow to stand, and inspect for droplets of a layer of water.	High humidity, extreme temperature changes.	For droplets, use one or two cans of commercial gas line anti-freeze. For a layer of water, the tank must be drained, and the fuel lines blown out with compressed air.

SECTION 6—ENGINE COMPRESSION

Test and Procedure	Results and Indications	Proceed to
6.1 Test engine compression: Remove all spark plugs. Block the throttle wide open. Insert a compression gauge into a spark plug port, crank the engine to obtain the maximum reading, and record.	If compression is within limits on all cylinders	7.1
	If gauge reading is extremely low on all cylinders	6.2
	If gauge reading is low on one or two cylinders: (If gauge readings are identical and low on two or more adjacent cylinders, the head gasket must be replaced.)	6.2

Checking compression

6.2 Test engine compression (wet): Squirt approximately 30 cc. of engine oil into each cylinder, and re-test per 6.1.	If the readings improve, worn or cracked rings or broken pistons are indicated: If the readings do not improve, burned or excessively carboned valves or a jumped timing chain are indicated. NOTE: A jumped timing chain is often indicated by difficult cranking.	See Car Section 7.1
--	--	----------------------------

SECTION 7—ENGINE VACUUM

Test and Procedure	Results and Indications	Proceed to
7.1 Attach a vacuum gauge to the intake manifold beyond the throttle plate. Start the engine, and observe the action of the needle over the range of engine speeds.	See below.	See below
 Normal engine Gauge reading: Steady, from 17–22 in./Hg.	INDICATION: Normal engine in good condition Proceed to: 8.1	
 Sticking valves Gauge reading: Intermittent fluctuation at idle	INDICATION: Sticking valves or ignition miss Proceed to: 9.1, 8.3	
 Incorrect valve timing Gauge reading: Low (10–15 in./Hg) but steady	INDICATION: Late ignition or valve timing, low compression, stuck throttle valve, leaking carburetor or manifold gasket Proceed to: 6.1	
 Carburetor requires adjustment Gauge reading: Drifting needle	INDICATION: Improper carburetor adjustment or minor intake leak. Proceed to: 7.2	
 Blown head gasket Gauge reading: Needle fluctuates as engine speed increases	INDICATION: Ignition miss, blown cylinder head gasket, leaking valve or weak valve spring Proceed to: 8.3, 6.1	
 Burnt or leaking valves Gauge reading: Steady needle, but drops regularly	INDICATION: Burnt valve or faulty valve clearance: Needle will fall when defective valve operates Proceed to: 9.1	
 Clogged exhaust system Gauge reading: Gradual drop in reading at idle White pointer = steady gauge hand	INDICATION: Choked muffler, excessive back pressure in system Proceed to: 10.1	
 Worn valve guides Gauge reading: Needle vibrates excessively at idle, but steadies as engine speed increases Black pointer = fluctuating gauge hand	INDICATION: Worn valve guides Proceed to: 9.1	

Test and Procedure	Results and Indications	Proceed To
7.2 Attach a vacuum gauge per 7.1, and test for an intake manifold leak. Squirt a small amount of oil around the intake manifold gaskets, carburetor gaskets, plugs and fittings. Observe the action of the vacuum gauge.	If the reading improves, replace the indicated gasket, or seal the indicated fitting or plug: If the reading remains low:	8.1 7.3
7.3 Test all vacuum hoses and accessories for leaks as described in 7.2. Also check the carburetor body (dashpots, automatic choke mechanism, throttle shafts) for leaks in the same manner.	If the reading improves, service or replace the offending part(s): If the reading remains low:	8.1 6.1

SECTION 8—SECONDARY ELECTRICAL SYSTEM

Test and Procedure	Results and Indications	Proceed to
8.1 Remove the distributor cap and check to make sure that the rotor turns when the engine is cranked. Visually inspect the distributor components.	Clean, tighten or replace any components which appear defective.	8.2
8.2 Connect a timing light (per manufacturer's recommendation) and check the dynamic ignition timing. Disconnect and plug the vacuum hose(s) to the distributor if specified, start the engine, and observe the timing marks at the specified engine speed.	If the timing is not correct, adjust to specifications by rotating the distributor in the engine: (Advance timing by rotating distributor opposite normal direction of rotor rotation, retard timing by rotating distributor in same direction as rotor rotation.)	8.3
8.3 Check the operation of the distributor advance mechanism(s): To test the mechanical advance, disconnect the vacuum lines from the distributor advance unit and observe the timing marks with a timing light as the engine speed is increased from idle. If the mark moves smoothly, without hesitation, it may be assumed that the mechanical advance is functioning properly. To test vacuum advance and or retard systems, alternately crimp and release the vacuum line, and observe the timing mark for movement. If movement is noted, the system is operating.	If the systems are functioning If the systems are not functioning, remove the distributor, and test on a distributor tester.	8.4 8.4
8.4 Locate an ignition miss: With the engine running, remove each spark plug wire, one at a time, until one is found that doesn't cause the engine to roughen and slow down. CAUTION: Do not pull on the wire to remove the boot from the plug. Be sure your hand is insulated from the wire.	When the missing cylinder is identified	4.1

SECTION 9—VALVE TRAIN

Test and Procedure	Results and Indications	Proceed to
9.1 Evaluate the valve train: Remove the valve cover, and ensure that the valves are adjusted to specifications. A mechanic's stethoscope may be used to aid in the diagnosis of the valve train. By pushing the probe on or near push rods or rockers, valve noise often can be isolated. A timing light also may be used to diagnose valve problems. Connect the light according to manufacturer's recommendations, and start the engine. Vary the firing moment of the light by increasing the engine speed (and therefore the ignition advance), and moving the trigger from cylinder to cylinder. Observe the movement of each valve.	Sticking valves or erratic valve train motion can be observed with the timing light. The cylinder head must be disassembled for repairs.	See Car Section
9.2 Check the valve timing: Locate top dead center of the No. 1 piston, and install a degree wheel or tape on the crankshaft pulley or damper with zero corresponding to an index mark on the engine. Rotate the crankshaft in its direction of rotation, and observe the opening of the No. 1 cylinder intake valve. The opening should correspond with the correct mark on the degree wheel according to specifications.	If the timing is not correct, the timing cover must be removed for further investigation.	See Car Section

SECTION 10—EXHAUST SYSTEM

Test and Procedure	Results and Indications	Proceed to
10.1 Determine whether the exhaust manifold heat control valve is operating: Operate the valve by hand to determine whether it is free to move. If the valve is free, run the engine to operating temperature and observe the action of the valve, to ensure that it is opening.	If the valve sticks, spray it with a suitable solvent, open and close the valve to free it, and retest. If the valve functions properly If the valve does not free, or does not operate, replace the valve.	10.2 10.2
10.2 Ensure that there are no exhaust restrictions: Visually inspect the exhaust system for kinks, dents, or crushing. Also note that gases are flowing freely from the tailpipe at all engine speeds, indicating no restriction in the muffler or resonator.	Replace any damaged portion of the system.	11.1

SECTION 11—COOLING SYSTEM

Test and Procedure	Results and Indications	Proceed to
11.1 Visually inspect the fan belt for glazing, cracks, and fraying, and replace if necessary. Tighten the belt so that the longest span has approximately 1/2" play at its mid-point under thumb pressure (see Maintenance Section).	Replace or tighten the fan belt as necessary.	11.2
 Checking belt tension		
11.2 Check the fluid level of the cooling system.	If full or slightly low, fill as necessary. If extremely low	11.5 11.3
11.3 Visually inspect the external portions of the cooling system (radiator, radiator hoses, thermostat elbow, water pump seals, heater hoses, etc.) for leaks. If none are found, pressurize the cooling system to 14–15 psi.	If cooling system holds the pressure If cooling system loses pressure rapidly, reinspect external parts of the system for leaks under pressure. If none are found, check dipstick for coolant in crankcase. If no coolant is present, but pressure loss continues If coolant is evident in crankcase, remove cylinder head(s), and check gasket(s). If gaskets are intact, block and cylinder head(s) should be checked for cracks or holes. If the gasket(s) is blown, replace, and purge the crankcase of coolant. NOTE: Occasionally, due to atmospheric and driving conditions, condensation of water can occur in the crankcase. This causes the oil to appear milky white. To remedy, run the engine until hot, and change the oil and oil filter.	11.5 11.4 12.6
11.4 Check for combustion leaks into the cooling system: Pressurize the cooling system as above. Start the engine, and observe the pressure gauge. If the needle fluctuates, remove each spark plug wire, one at a time, noting which cylinder(s) reduce or eliminate the fluctuation.	Cylinders which reduce or eliminate the fluctuation, when the spark plug wire is removed, are leaking into the cooling system. Replace the head gasket on the affected cylinder bank(s).	See Car Section

Pressurizing the cooling system

26 TROUBLESHOOTING

Test and Procedure	Results and Indications	Proceed To
11.5 Check the radiator pressure cap: Attach a radiator pressure tester to the radiator cap (wet the seal prior to installation). Quickly pump up the pressure, noting the point at which the cap releases.	If the cap releases within ± 1 psi of the specified rating, it is operating properly.	11.6
	If the cap releases at more than ± 1 psi of the specified rating, it should be replaced.	11.6
 Checking radiator pressure cap		
11.6 Test the thermostat: Start the engine cold, remove the radiator cap, and insert a thermometer into the radiator. Allow the engine to idle. After a short while, there will be a sudden, rapid increase in coolant temperature. The temperature at which this sharp rise stops is the thermostat opening temperature.	If the thermostat opens at or about the specified temperature	11.7
	If the temperature doesn't increase (If the temperature increases slowly and gradually, replace the thermostat.)	11.7
11.7 Check the water pump: Remove the thermostat elbow and the thermostat, disconnect the coil high tension lead (to prevent starting), and crank the engine momentarily.	If coolant flows, replace the thermostat and retest per 11.6.	11.6
	If coolant doesn't flow, reverse flush the cooling system to alleviate any blockage that might exist. If system is not blocked, and coolant will not flow, replace the water pump.	See Car Section

SECTION 12—LUBRICATION

Test and Procedure	Results and Indications	Proceed to
12.1 Check the oil pressure gauge or warning light: If the gauge shows low pressure, or the light is on for no obvious reason, remove the oil pressure sender. Install an accurate oil pressure gauge and run the engine momentarily.	If oil pressure builds normally, run engine for a few moments to determine that it is functioning normally, and replace the sender.	—
	If the pressure remains low	12.2
	If the pressure surges	12.3
	If the oil pressure is zero	12.3
12.2 Visually inspect the oil: If the oil is watery or very thin, milky, or foamy, replace the oil and oil filter.	If the oil is normal	12.3
	If after replacing oil the pressure remains low	12.3
	If after replacing oil the pressure becomes normal	—
12.3 Inspect the oil pressure relief valve and spring, to ensure that it is not sticking or stuck. Remove and thoroughly clean the valve, spring, and the valve body.	If the oil pressure improves	—
	If no improvement is noted	12.4

Test and Procedure	Results and Indications	Proceed To
12.4 Check to ensure that the oil pump is not cavitating (sucking air instead of oil): See that the crankcase is neither over nor underfull, and that the pickup in the sump is in the proper position and free from sludge.	Fill or drain the crankcase to the proper capacity, and clean the pickup screen in solvent if necessary. If no improvement is noted	12.5
12.5 Inspect the oil pump drive and the oil pump:	If the pump drive or the oil pump appear to be defective, service as necessary and retest per 12.1. If the pump drive and pump appear to be operating normally, the engine should be disassembled to determine where blockage exists.	12.1
12.6 Purge the engine of ethylene glycol coolant: Completely drain the crankcase and the oil filter. Obtain a commercial butyl cellosolve base solvent, designated for this purpose, and follow the instructions precisely. Following this, install a new oil filter and refill the crankcase with the proper weight oil. The next oil and filter change should follow shortly thereafter (1000 miles).		

Diesel Engine Troubleshooting

NOTE: The following troubleshooting procedures cover problems usually associated with diesel engines. Those problems common to both gasoline and diesel engines are covered in the gasoline engine troubleshooting procedures.

INDEX TO PROBLEMS

Problem/Symptom	Begin at Specific Diagnosis, Number
Fuel System	Section 1
Engine Starting Difficulty:	
Feed pump does not feed fuel	1.1
Injection pump does not feed fuel	1.2
Incorrect injection timing	1.3
Defective injection nozzles	1.4
Engine Operating Instability:	
Engine shuts off immediately after starting	1.5
Uneven idling	1.6
Engine will not reach maximum rated speed	1.7
Engine exceeds maximum rated speed	1.8
Loss of power	1.9
Engine Knock:	
Associated with exhaust gas problems	1.10
Not associated with exhaust gas problems	1.11
Engine Mechanical	Section 2
Engine Starting Difficulty	2.1
Unusual Noises	2.2
Engine Operating Instability	2.3
Loss of Power	2.4
Exhaust gas Problem	2.5
Engine Shut-Off	2.6
Loss of Oil Pressure	2.7
Oil Leakage	2.8
Compression Pressure Leakage	2.9

SECTION 1—Fuel System

Test and Procedure	Results and Indication	Proceed To
1.1a Check for pressure at the outlet of the feed pump	If pressure exists, there is a clog in the supply line. Clean or replace it. If there is little or no pressure at the outlet, the filter is clogged. Clean or replace the filter. If the filter is clear, the feed pump piston is inoperative. Relace it.	1.1b
1.1b Check the feed pump valves	If the inlet and outlet valves do not operate, the check valve or spring is broken. Replace it.	1.2a
1.2a Check for fuel leakage at the overflow or return line	A clogged filter can result in high pressure causing leakage. Replace the filter.	1.2b
1.2b Check for fuel in the filter leaking at the overflow valve	If leakage is found, the overflow valve is damaged. Replace it.	1.2c
1.2c Check for leakage at the injection pump overflow valve	If leakage is found, it is caused by: damaged overflow valve, sticking plunger, or sticking delivery valve. Replace the defective part(s).	1.2d
1.2d Check the injection pump plunger feed pressures.	If pressure at the plungers is low, replace the plunger(s).	1.2e

Test and Procedure		Results and Indication	Proceed To
1.2e	Check to make sure the injection pump is operating	An inoperative pump is caused by: a damaged or missing shaft key, or a damaged drive gear train.	1.3a
1.3a	Check that the pump timing marks are correctly aligned in the gear train	Incorrect timing marks alignment must be corrected.	1.3b
1.3b	Check that the injection pump is properly mounted	Remove and install the pump correctly	1.4a
1.4a	Install an injection nozzle on a tester and make sure that fuel is continuously ejected	A broken or intermittent stream is caused by a damaged spring or a sticking nozzle needle	1.4b
1.4b	With the nozzle on the tester as in 1.4a, check that shutoff is clean with no dribble or afterdrip	Dribble is caused by a defective nozzle valve seat. Replace the nozzle.	1.4c
1.4c	Using a tester, check injection pressure	Low pressure is a result of a weak spring. Replace the spring or adjust the initial injection pressure.	1.5a
1.5a	See 1.2a	Proceed as in 1.2a	1.5b
1.5b	Check for water in the fuel	Drain and clean the tank	1.5c
1.5c	Check for air in the fuel lines.	Air can be introduced through a damaged fuel inlet line, a loose inlet line connector or a damaged gasket	1.5d
1.5d	Check for insufficient fuel feed	Insufficient fuel feed is caused by: a damaged feed pump, a clogged tank vent, or a clogged filter. Replace or repair as necessary.	1.6a
1.6a	Check the control rack action for smooth operation	Uneven control rack operation is caused by: a sticking plunger, improper meshing of the rack and pinion, poor seating of the plunger spring, insufficient clearance between the plunger and lower spring seat, or an overly tight delivery valve holder. Replace or adjust as necessary.	1.6b
1.6b	Check that the injection pump discharge is uniform	If the output is uneven, adjust as necessary	1.6c
1.6c	Check that the injection pump discharge volume is adequate	An inadequate discharge volume is caused by a worn plunger or a broken spring	1.6d
1.6d	Check for even low speed engine performance	If the engine performs unevenly or erratically at low speed only, a worn feed pump piston or defective feed pump valve is the cause.	1.6e
1.6e	Check for smooth engine operation throughout the operating range	This problem is usually caused by mechanical governor defects such as: a defective low speed spring, defective damper spring, or excessive friction among moving parts. Replace the defective parts.	1.6f
1.6f	Check the injectors on a tester	Improper nozzle operation should be corrected accordingly	1.7a
1.7a	Check the operating governor	A broken or weak spring in the governor will prevent full speed operation.	1.7b
1.7b	Check the injectors on a tester for a drop in injector output	A drop in output is caused by a sticking needle or a dirty nozzle. Replace or clean as necessary.	1.8a

26 TROUBLESHOOTING

Test and Procedure		Results and Indications	Proceed To
1.8a	Check the injection pump for proper rack and pinion action	A catching or dirty rack and pinion will cause overspeeding.	1.8b
1.8b	Check the governor adjustment	An improperly adjusted governor will cause overspeeding. Adjust.	1.9a
1.9a	Check the injection pump output	Low output can be caused by: Incorrect adjustment—Adjust Loose delivery valve—Tighten Broken delivery valve seal—Replace Poor valve seat contact—Replace Broken/weak delivery valve spring—Replace	1.9b
1.9b	Check for unusual noise at the injection pump	A noisy pump is an indication of a broken plunger spring	1.9c
1.9c	Check plunger operation	A sticking injection pump plunger will cause power loss. Replace.	1.9d
1.9d	Check the injection timer	A lag in injection timing is caused by large clearances in the timer due to wear. Replace.	1.9e
1.9e	Check for air or water in the fuel	Bleed the air or drain the fuel and clean the tank and lines	1.9f
1.9f	Check the injection timing	Readjust timing if necessary	1.10a
1.10a	Check the initial injection timing	Adjust if necessary	1.10b
1.10b	Check the injection pressure	High pressure will cause knock. Adjust as necessary	1.10c
1.10c	Check the injector nozzle	A clogged nozzle causes knock. Clean or replace the nozzle.	1.11a
1.11a	Check the injection pump output and timing	Excessive output, coupled with incorrect timing causes knock. Adjust as necessary	1.11b
1.11b	Check the delivery valve seat	Replace a defective seat	1.11c
1.11c	Check the pump plungers	Replace badly worn plungers	1.11d
1.11d	Check injector opening pressure on a tester	Adjust as necessary	1.11e
1.11e	Check the injector	Replace a broken nozzle spring or sticking needle.	

SECTION 2—ENGINE MECHANICAL

Test and Procedure		Results and Indications	Proceed To
2.1a	Check for piston seizing	Seized pistons are caused by low oil pressure, oil breakdown, or overheating. Replace the pistons and liners.	2.1b
2.1b	Check for a damaged flywheel ring gear	A damaged ring gear will cause poor meshing with the starter. Replace the ring gear.	2.1c
2.1c	Make a compression check	Low compression can be caused by: sticking rings, worn rings, worn liners. Replace the rings or liners.	2.2a
2.2a	A knocking noise at idle or during acceleration can be caused by a variety of wear problems.	Use a stethoscope or similar listening device to try to pinpoint the source of the noise. Among other reasons for knocking are: piston pins, rod bearings, loose rod caps, crankshaft journals and/or bearings, crankshaft thrust washer. Replace any worn parts.	2.2b
2.2b	An infrequently encountered noise is a continuous growl during acceleration	This problem is usually caused by problems in the engine timing gears. Poor contact, excessive backlash or loose gears are usually at fault.	2.2c
2.2c	Intermittent noises are the hardest to find. They are usually caused by broken moving parts.	Check the gear train for a chipped or cracked gear; the oil pan for broken parts or foreign objects or the cylinder head for a broken valve or valve spring.	2.3
2.3	Check for oil in the combustion chambers	Oil entering the combustion chambers will cause the engine to overspeed if the amount of oil is too great, or run unevenly. Check for broken or sticking rings, bad head gasket(s) or worn valve guides.	2.4
2.4	Check the compression	Low compression is the main cause of power loss. The main causes for low compression are: worn rings or liners, cracked valves, warped head or block, and bad head gasket.	2.5
2.5	A large amount of black exhaust is caused by low compression	See 2.4 above	2.6
2.6	If the engine stops suddenly during operation, the cause is usually sudden damage	Check the pistons, main bearings or rod bearings for lack of lubrication. A seized camshaft is also a result of low or no lubrication. Check the timing gears for damage.	2.7
2.7	Check for excessive clearance between the bearings and journals on both the mains and rod bearings. Check the oil pressure.	Replace as necessary. Replace the pump as necessary.	2.8
2.8	Aside from the usual leaking gasket problems, check the condition of the combustion chamber O-rings.	Replace as necessary	2.9
2.9	Compression leakage is usually caused by a seal defect between the head and the block	Check the head gasket; check for loose head bolts; check for head or block warpage. Replace or repair as necessary.	

Engine Overheating Troubleshooting

Engine Overheating Troubleshooting

Low Engine Temperature Troubleshooting

DRIVELINE

Clutch System Troubleshooting

Condition	Possible Cause	Corrective Action
Clutch chatter	1. Grease on driven plate (disc) facing. 2. Binding clutch linkage. 3. Loose, damaged facings on driven plate (disc). 4. Engine mounts loose. 5. Incorrect height adjustment of pressure plate release levers. 6. Clutch housing or housing to transmission adapter misalignment. 7. Loose driven plate hub.	1. Replace plate. 2. Check for worn, bent, broken parts. Replace as required. Lube linkage. 3. Replace driven plate. 4. Tighten mounts. Replace if damaged. 5. Adjust release lever height. 6. Check bore and face run out. Correct as required. 7. Replace driven plate.
Clutch grabbing	1. Oil, grease on driven plate (disc) facing. 2. Broken pressure plate. 3. Warped or binding driven plate. Driven plate binding on clutch shaft.	1. Replace driven plate. 2. Replace pressure plate. 3. Replace warped driven plate. Replace clutch shaft if defective, scored, worn.
Clutch slips	1. Lack of lubrication in clutch linkage (linkage binds, causes incomplete engagement). 2. Incorrect pedal, or linkage adjustment. 3. Broken pressure plate springs. 4. Weak pressure plate springs. 5. Grease on driven plate facings (disc).	1. Lubricate linkage. 2. Adjust as required. 3. Replace pressure plate. 4. Replace pressure plate. 5. Replace driven plate.
Incomplete clutch release	1. Incorrect pedal or linkage adjustment or linkage binding. 2. Incorrect height adjustment on pressure plate release levers. 3. Loose, broken facings on driven plate (disc). 4. Bent, dished, warped driven plate caused by overheating.	1. Adjust as required. Lubricate linkage. 2. Adjust release lever height. 3. Replace driven plate. 4. Replace driven plate.
Grinding, whirring grating noise when pedal is depressed	1. Worn or defective throwout bearing. 2. Starter drive teeth contacting flywheel ring gear teeth.	1. Replace throwout bearing. 2. Look for milled or polished teeth on ring gear. Align clutch housing, replace starter drive or drive spring as required.
Squeal, howl, trumpeting noise when pedal is being released (occurs during first inch to inch and one-half of pedal travel)	1. Pilot bushing worn or lack of lubricant.	1. Replace worn bushing. If bushing appears OK, polish bushing with emery, soak lube wick in oil, lube bushing with oil, apply film of chassis grease to clutch shaft pilot hub, reassemble. NOTE: Bushing wear may be due to misalignment of clutch housing or housing to transmission adapter.
Vibration or clutch pedal pulsation with clutch disengaged (pedal fully depressed)	1. Worn or defective engine transmission mounts. 2. Flywheel run out, or damaged or defective clutch components.	1. Inspect and replace as required. 2. Replace components as required. (Flywheel run out at face not to exceed 0.005").

Manual Transmission Troubleshooting

Condition	Probable Cause
Jumping out of high gear	1. Misalignment of transmission case or clutch housing. 2. Worn pilot bearing in crankshaft. 3. Bent transmission shaft. 4. Worn high speed sliding gear. 5. Worn teeth in clutch shaft. 6. Insufficient spring tension on shifter rail plunger. 7. Bent or loose shifter fork. 8. End-play in clutch shaft. 9. Gears not engaging completely. 10. Loose or worn bearings on clutch shaft or mainshaft.
Sticking in high gear	1. Clutch not releasing fully. 2. Burred or battered teeth on clutch shaft. 3. Burred or battered transmission mainshaft. 4. Frozen synchronizing clutch. 5. Stuck shifter rail plunger. 6. Gearshift lever twisting and binding shifter rail. 7. Battered teeth on high speed sliding gear or on sleeve. 8. Lack of lubrication. 9. Improper lubrication. 10. Corroded transmission parts. 11. Defective mainshaft pilot bearing.
Jumping out of second gear	1. Insufficient spring tension on shifter rail plunger. 2. Bent or loose shifter fork. 3. Gears not engaging completely. 4. End-play in transmission mainshaft. 5. Loose transmission gear bearing. 6. Defective mainshaft pilot bearing. 7. Bent transmission shaft. 8. Worn teeth on second speed sliding gear or sleeve. 9. Loose or worn bearings on transmission mainshaft. 10. End-play in countershaft.
Sticking in second gear	1. Clutch not releasing fully. 2. Burred or battered teeth on sliding sleeve. 3. Burred or battered transmission mainshaft. 4. Frozen synchronizing clutch. 5. Stuck shifter rail plunger. 6. Gearshift lever twisting and binding shifter rail. 7. Lack of lubrication. 8. Second speed transmission gear bearings locked will give same effect as gears stuck in second. 9. Improper lubrication. 10. Corroded transmission parts.
Jumping out of low gear	1. Gears not engaging completely. 2. Bent or loose shifter fork. 3. End-play in transmission mainshaft. 4. End-play in countershaft. 5. Loose or worn bearings on transmission mainshaft. 6. Loose or worn bearings in countershaft. 7. Defective mainshaft pilot bearing.
Sticking in low gear	1. Clutch not releasing fully. 2. Burred or battered transmission mainshaft. 3. Stuck shifter rail plunger. 4. Gearshift lever twisting and binding shifter rail. 5. Lack of lubrication. 6. Improper lubrication. 7. Corroded transmission parts.

Condition	Probable Cause
Jumping out of reverse gear	1. Insufficient spring tension on shifter rail plunger. 2. Bent or loose shifter fork. 3. Badly worn gear teeth. 4. Gears not engaging completely. 5. End-play in transmission mainshaft. 6. Idler gear bushings loose or worn. 7. Loose or worn bearings on transmission mainshaft. 8. Defective mainshaft pilot bearing.
Sticking in reverse gear	1. Clutch not releasing fully. 2. Burred or battered transmission mainshaft. 3. Stuck shifter rail plunger. 4. Gearshift lever twisting and binding shifter rail. 5. Lack of lubrication. 6. Improper lubrication. 7. Corroded transmission parts.
Failure of gears to synchronize	1. Binding pilot bearing on mainshaft, will synchronize in high gear only. 2. Clutch not releasing fully. 3. Detent spring weak or broken. 4. Weak or broken springs under balls in sliding gear sleeve. 5. Binding bearing on clutch shaft. 6. Binding countershaft. 7. Binding pilot bearing in crankshaft 8. Badly worn gear teeth. 9. Scored or worn cones. 10. Improper lubrication. 11. Constant mesh gear not turning freely on transmission mainshaft. Will synchronize in that gear only.
Gears spinning when shifting into gear from neutral	1. Clutch not releasing fully. 2. In some cases an extremely light lubricant in transmission will cause gears to continue to spin for a short time after clutch is released. 3. Binding pilot bearing in crankshaft.
Noisy in all gears	1. Insufficient lubricant. 2. Worn countergear bearings. 3. Worn or damaged main drive gear or countergear. 4. Damaged main drive gear or mainshaft bearings. 5. Worn or damaged countergear anti-lash plate.
Noisy in high gear	1. Damaged main drive gear bearing. 2. Damaged mainshaft bearing. 3. Damaged high speed gear synchronizer.
Noisy in neutral	1. Damaged main drive gear bearing. 2. Damaged or loose mainshaft pilot bearing. 3. Worn or damaged countergear anti-lash plate. 4. Worn countergear bearings.
Noisy in all reduction gears	1. Insufficient lubricant. 2. Worn or damaged drive gear or countergear.
Noisy in second only	1. Damaged or worn second gear constant mesh gears. 2. Worn or damaged countergear rear bearings. 3. Damaged or worn second gear synchronizer.
Noisy in second only	1. Damaged or worn second gear constant mesh gears. 2. Worn or damaged countergear rear bearings. 3. Damaged or worn second gear synchronizer.
Noisy in third only (four speed)	1. Damaged or worn third gear constant mesh gears. 2. Worn or damaged countergear bearings.

26 TROUBLESHOOTING

Condition	Probable Cause
Noisy in reverse only	1. Worn or damaged reverse idler gear or idler bushing. 2. Worn or damaged mainshaft reverse gear. 3. Worn or damaged reverse countergear. 4. Damaged shift mechanism.
Excessive backlash in all reduction gears	1. Worn countergear bearings. 2. Excessive end-play in countergear.

Automatic Transmission Troubleshooting

Keeping alert to changes in the operating characteristics of the transmission (changing shift points, noises, etc.) can prevent small problems from becoming large ones. If the problem cannot be traced to loose bolts, fluid level, misadjusted linkage, clogged filters or similar problems, you should probably seek professional service.

TRANSMISSION FLUID INDICATIONS

The appearance and odor of the transmission fluid can give valuable clues to the overall condition of the transmission. Always note the appearance of the fluid when you check the fluid level or change the fluid. Rub a small amount of fluid between your fingers to feel for grit and smell the fluid on the dipstick.

If The Fluid Appears	It Indicates
Clear and red colored	Normal operation
Discolored (extremely dark red or brownish) or smells burned	Band or clutch pack failure, usually caused by an overheated transmission. Hauling very heavy loads with insufficient power or failure to change the fluid often results in overheating. Do not confuse this appearance with newer fluids that have a darker red color and a strong odor (though not a burned odor).
Foamy or aerated (light in color and full of bubbles)	The level is too high (gear train is churning oil) An internal air leak (air is mixing with the fluid). Have the transmission checked professionally.
Solid residue in the fluid	Defective bands, clutch pack or bearings. Bits of band material or metal abrasives are clinging to the dipstick. Have the transmission checked professionally.
Varnish coating on the dipstick	The transmission fluid is overheating

Problem	Possible Cause	Correction
Slow initial engagement	1. Improper fluid level. 2. Damaged or improperly adjusted linkage. 3. Contaminated fluid. 4. Faulty clutch and band application, or oil control pressure system.	1. Add fluid as required. 2. Repair or adjust linkage. 3. Perform fluid level check. 4. Perform control pressure test.
Rough initial engagement in either forward or reverse	1. Improper fluid level. 2. High engine idle. 3. Looseness in the driveshaft, U-joints or engine mounts. 4. Incorrect linkage adjustment. 5. Faulty clutch or band application, or oil control pressure system. 6. Sticking or dirty valve body.	1. Perform fluid level check. 2. Adjust idle to specifications. 3. Repair as required. 4. Repair or adjust linkage. 5. Perform control pressure test. 6. Clean, repair or replace valve body.

Problem	Possible Cause	Correction
No drive, slips or chatters in first gear in D. All other gears normal.	1. Faulty one-way clutch.	1. Repair or replace one-way clutch.
No drive, slips or chatters in second gear.	1. Improper fluid level. 2. Damaged or improperly adjusted linkage. 3. Intermediate band out of adjustment. 4. Faulty band or clutch application, or oil pressure control system. 5. Faulty servo and/or internal leaks. 6. Dirty or sticking valve body. 7. Polished, glazed intermediate band or drum.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Adjust intermediate band. 4. Perform control pressure test. 5. Perform air pressure test. 6. Clean, repair or replace valve body. 7. Replace or repair as required.
No drive in any gear.	1. Improper fluid level. 2. Damaged or improperly adjusted linkage. 3. Faulty clutch or band application, or oil control pressure system. 4. Internal leakage. 5. Valve body loose. 6. Faulty clutches. 7. Sticking or dirty valve body.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Perform control pressure test. 4. Check and repair as required. 5. Tighten to specification. 6. Perform air pressure test. 7. Clean, repair or replace valve body.
No drive forward—reverse OK.	1. Improper fluid level 2. Damaged or improperly adjusted linkage. 3. Faulty clutch or band application, or oil pressure control system. 4. Faulty forward clutch or governor. 5. Valve body loose 6. Dirty or sticking valve body.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Perform control pressure test. 4. Perform air pressure test. 5. Tighten to specification. 6. Clean, repair or replace valve body.
No drive, slips or chatters in reverse—forward OK.	1. Improper fluid level 2. Damaged or improperly adjusted linkage. 3. Looseness in the driveshaft, U-joints or engine mounts. 4. Bands or clutches out of adjustment. 5. Faulty oil pressure control system. 6. Faulty reverse clutch or servo. 7. Valve body loose. 8. Dirty or sticking valve body.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Repair as required. 4. Adjust as necessary. 5. Perform control pressure test. 6. Perform air pressure test. 7. Tighten to specifications. 8. Clean, repair or replace valve body.
Starts in high—in D drag or lockup at 1–2 shift point or in 2 or 1.	1. Improper fluid level. 2. Damaged or improperly adjusted linkage. 3. Faulty governor. 4. Faulty clutches and/or internal leaks. 5. Valve body loose. 6. Dirty, sticking valve body. 7. Poor mating of valve body to case mounting surfaces.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Repair or replace governor, clean screen. 4. Perform air pressure test. 5. Tighten to specifications. 6. Clean, repair or replace valve body. 7. Replace valve body or case.

26 TROUBLESHOOTING

Problem	Possible Cause	Correction
Starts up in 2nd or 3rd but no lockup at 1-2 shift points.	1. Improper fluid level. 2. Damaged or improperly adjusted linkage. 3. Improper band and/or clutch application, or oil pressure control system. 4. Faulty governor. 5. Valve body loose. 6. Dirty or sticking valve body. 7. Cross leaks between valve body and case mating surface.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Perform control pressure test. 4. Perform governor check. Replace or repair governor, clean screen. 5. Tighten to specification. 6. Clean, repair or replace valve body. 7. Replace valve body and/or case as required.
Shift points incorrect.	1. Improper fluid level. 2. Improper vacuum hose routing or leaks. 3. Improper operation of EGR system. 4. Linkage out of adjustment. 5. Improper speedometer gear installed. 6. Improper clutch or band application, or oil pressure control system. 7. Faulty governor. 8. Dirty or sticking valve body.	1. Perform fluid level check. 2. Correct hose routing. 3. Repair or replace as required. 4. Repair or adjust linkage. 5. Replace gear. 6. Perform shift test and control pressure test. 7. Repair or replace governor—clean screen. 8. Clean, repair or replace valve body.
No upshift at any speed in D.	1. Improper fluid level. 2. Vacuum leak to diaphragm unit. 3. Linkage out of adjustment. 4. Improper band or clutch application, or oil pressure control system. 5. Faulty governor. 6. Dirty or sticking valve bdy.	1. Perform fluid level check. 2. Repair vacuum line or hose. 3. Repair or adjust linkage. 4. Perform control pressure test. 5. Repair or replace governor, clean screen. 6. Clean, repair or replace valve body.
Shifts 1-3 in D.	1. Improper fluid level. 2. Intermediate band out of adjustment. 3. Faulty front servo and/or internal leaks. 4. Polished, glazed band or drum. 5. Improper band or clutch application, or oil pressure control system. 6. Dirty or sticking valve body.	1. Perform fluid level check. 2. Adjust band. 3. Perform air pressure test. Repair front servo and/or internal leaks. 4. Repair or replace band or drum. 5. Perform control pressure test. 6. Clean, repair or replace valve body.
Engine over-speeds on 2-3 shift.	1. Improper fluid level. 2. Linkage out of adjustment. 3. Improper band or clutch application, or oil pressure control system. 4. Faulty high clutch and/or intermediate servo. 5. Dirty or sticking valve body.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Perform control pressure test. 4. Perform air pressure test. Repair as required. 5. Clean repair or replace valve body.
Mushy 1-2 shift.	1. Improper fluid level 2. Incorrect engine idle and/or performance. 3. Improper linkage adjustment. 4. Intermediate band out of adjustment.	1. Perform fluid level check. 2. Tune, adjust engine idle as required. 3. Repair or adjust linkage. 4. Adjust intermediate band. 5. Perform control pressure test.

Problem	Possible Cause	Correction
Mushy 1-2 shift.	- Improper band or clutch application, or oil pressure control system. - Faulty high clutch and/or intermediate servo release. - Polished, glazed band or drum. - Dirty or sticking valve body.	- Perform air pressure test. Repair as required. - Repair or replace as required. - Clean, repair or replace valve body.
Rough 1-2 shift.	- Improper fluid level. - Incorrect engine idle or performance. - Intermediate band out of adjustment. - Improper band or clutch application, or oil pressure control system. - Faulty intermediate servo. - Dirty or sticking valve body.	- Perform fluid level check. - Tune, and adjust engine idle. - Adjust intermediate band. - Perform control pressure test. - Air pressure check intermediate servo. - Clean, repair or replace valve body.
Rough 2-3 shift	- Improper fluid level. - Incorrect engine idle or performance. - Improper band or clutch application, or oil control pressure system. - Faulty intermediate servo apply and release and high clutch piston check ball. - Dirty or sticking valve body.	- Perform fluid level check. - Tune and adjust engine idle. - Perform control pressure test. - Air pressure test the intermediate servo apply and release and the high clutch piston check ball. Repair as required. - Clean, repair or replace valve body.
Rough 3-1 shift at closed throttle in D.	- Improper fluid level. - Incorrect engine idle or performance. - Improper linkage adjustment. - Improper clutch or band application or oil pressure control system. - Faulty governor operation. - Dirty or sticking valve body.	- Perform fluid level check. - Tune, and adjust engine idle. - Repair or adjust linkage. - Perform control pressure test. - Perform governor test. Repair as required. - Clean, repair or replace valve body.
No forced downshifts.	- Improper fluid level. - Linkage out of adjustment. - Improper clutch or band application, or oil pressure control system. - Faulty internal kickdown linkage. - Dirty or sticking valve body.	- Perform fluid level check. - Repair or adjust linkage. - Perform control pressure test. - Repair internal kickdown linkage. - Clean, repair or replace valve body.
No 3-1 shift in D.	- Improper fluid level. - Incorrect engine idle, or performance. - Faulty governor. - Dirty or sticking valve body.	- Perform fluid level check. - Tune, and adjust engine idle. - Perform governor check. Repair as required. - Clean, repair or replace valve body.
Runaway engine on 3-2 downshift.	- Improper fluid level. - Linkage out of adjustment. - Intermediate band out of adjustment. - Improper band or clutch application, or oil pressure control system.	- Perform fluid level check. - Repair or adjust linkage. - Adjust intermediate band. - Perform control pressure test. - Air pressure test check the intermediate servo. Repair servo and/or seals.

26 TROUBLESHOOTING

Problem	Possible Cause	Correction
Runaway engine on 3-2 downshift.	5. Faulty intermediate servo. 6. Polished, glazed band or drum. 7. Dirty or sticking valve body.	6. Repair or replace as required. 7. Clean, repair or replace valve body.
No engine braking in manual first gear.	1. Improper fluid level. 2. Linkage out of adjustment. 3. Bands or clutches out of adjustment. 4. Faulty oil pressure control system. 5. Faulty reverse servo. 6. Polished, glazed band or drum.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Adjust as necessary. 4. Perform control pressure test. 5. Perform air pressure test of reverse servo. Repair reverse clutch or rear servo as required. 6. Repair or replace as required.
No engine braking in manual second gear.	1. Improper fluid level. 2. Linkage out of adjustment. 3. Intermediate band out of adjustment. 4. Improper band or clutch application, or oil pressure control system. 5. Intermediate servo leaking. 6. Polished or glazed band or drum.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Adjust intermediate band. 4. Perform control pressure test. 5. Perform air pressure test of intermediate servo for leakage. Repair as required. 6. Repair or replace as required.
Transmission noisy—valve resonance.	1. Improper fluid level. 2. Linkage out of adjustment. 3. Improper band or clutch application, or oil pressure control system. 4. Cooler lines grounding. 5. Dirty sticking valve body. 6. Internal leakage or pump cavitation.	1. Perform fluid level check. 2. Repair or adjust linkage. 3. Perform control pressure test. 4. Free up cooler lines. 5. Clean, repair or replace valve body. 6. Repair as required.
Transmission overheats.	1. Improper fluid level. 2. Incorrect engine idle, or performance. 3. Improper clutch or band application, or oil pressure control system. 4. Restriction in cooler or lines. 5. Seized one-way clutch. 6. Dirty or sticking valve body.	1. Perform fluid level check. 2. Tune, or adjust engine idle. 3. Perform control pressure test. 4. Repair restriction. 5. Replace one-way clutch. 6. Clean, repair or replace valve body.
Transmission fluid leaks.	1. Improper fluid level. 2. Leakage at gasket, seals, etc. 3. Vacuum diaphragm unit leaking.	1. Perform fluid level check. 2. Remove all traces of lube on exposed surfaces of transmission. Check the vent for free breathing. Operate transmission at normal temperatures and inspect for leakage. Repair as required. 3. Replace diaphragm.

Automatic Transmission Troubleshooting

Driveshaft Troubleshooting Vibration, Roughness, Rumble and/or Boom

Universal Joint Troubleshooting

Problem	Possible Cause	Correction
Leak at front slip yoke. NOTE: An occasional drop of lubricant leaking from splined yoke is normal and requires no attention.	1. Rough outside surface on splined yoke. 2. Defective transmission rear oil seal.	1. Replace seal if cut by burrs on yoke. Minor burrs can be smoothed by careful use of crocus cloth or honing with a fine stone. Replace yoke if outside surface is rough or burred badly. 2. Replace transmission rear oil seal. 3. Bring transmission oil up to proper level after correction.
Knock in drive line, clunking noise when car is operated under floating condition at 10 mph in high gear or neutral.	1. Worn or damaged universal joints. 2. Side gear hub counterbore in differential worn oversize.	1. Disassemble universal joints, inspect and replace worn or damaged parts. 2. Replace differential case and/or side gears as required.
Ping, snap or click in drive line. NOTE: Usually occurs on initial load application after transmission has been put into gear, either forward or reverse.	1. Loose upper or lower control arm bushing bolts. 2. Loose companion flange.	1. Tighten bolts to specified torque. 2. Remove companion flange, turn 180° from its original position, apply white lead to splines and reinstall. Tighten pinion nut to specified torque.

Front Wheel Drive Halfshaft Troubleshooting

*Halfshafts do not usually contribute to rotational vibrations.

Drive Axle Troubleshooting

Condition	Possible Cause	Correction
Rear wheel noise	1. Loose wheel. 2. Spalled wheel bearing cup or cone. 3. Defective or brinelled wheel bearing. 4. Excessive axle shaft endplay. 5. Bent or sprung axle shaft flange.	1. Tighten loose wheel nuts. 2. Check rear wheel bearings. If spalled or worn, replace. 3. Defective or brinelled bearings must be replaced. Check rear axle shaft end play. 4. Readjust axle shaft end play. 5. Replace bent or sprung axle shaft.
Scoring of differential gears and pinions	1. Insufficient lubrication. 2. Improper grade of lubricant. 3. Excessive spinning of one wheel.	1. Replace scored gears. Scoring marks on the pressure face of gear teeth or in the bore are caused by instantaneous fusing of the mating surfaces. Scored gears should be replaced. Fill rear axle to required capacity with proper lubricant. 2. Replace scored gears. Inspect all gears and bearings for possible damage. Clean and refill axle to required capacity with proper lubricant. 3. Replace scored gears. Inspect all gears, pinion bores and shaft for scoring, or bearings for possible damage.
Tooth breakage (ring gear and pinion)	1. Overloading. 2. Erratic clutch operation. 3. Ice-spotted pavements. 4. Improper adjustments.	1. Replace gear. Examine other gears and bearings for possible damage. Avoid future overloading. 2. Replace gear, and examine remaining parts for possible damage. Avoid erratic clutch operation. 3. Replace gears. Examine remaining parts for possible damage. Replace parts as required. 4. Replace gears. Examine other parts for possible damage. Be sure ring gear and pinion backlash is correct.
Rear axle noise	1. Insufficient lubricant. 2. Improper ring gear and pinion adjustment. 3. Unmatched ring gear and pinion. 4. Worn teeth on ring gear or pinion. 5. End-play in drive pinion bearings. 6. Side play in differential bearings. 7. Incorrect drive gearlash. 8. Limited-slip differential—moan and chatter.	1. Refill rear axle with correct amount of the proper lubricant. Also check for leaks and correct as necessary. 2. Check ring gear and pinion tooth contact. 3. Remove unmatched ring gear and pinion. Replace with a new matched gear and pinion set. 4. Check teeth on ring gear and pinion for contact. If necessary, replace with new matched set. 5. Adjust drive pinion bearing preload.

Problem	Possible Cause	Correction
Rear axle noise		- Adjust differential bearing preload. - Correct drive gear lash. - Drain and flush lubricant. Refill with proper lubricant.
Loss of lubricant	- Lubricant level too high. - Worn axle shaft oil seals. - Cracked rear axle housing. - Worn drive pinion oil seal. - Scored and worn companion flange. - Clogged vent. - Loose carrier housing bolts or housing cover screws.	- Drain excess lubricant. - Replace worn oil seals with new ones. Prepare new seals before replacement. - Repair or replace housing as required. - Replace worn drive pinion oil seal with a new one. - Replace worn or scored companion flange and oil seal. - Remove obstructions. - Tighten bolts or cover screws to specifications and fill to correct level with proper lubricant.
Overheating of unit	- Lubricant level too low. - Incorrect grade of lubricant. - Bearing adjusted too tightly. - Excessive wear in gears. - Insufficient ring gear-to-pinion clearance.	- Refill rear axle. - Drain, flush and refill rear axle with correct amount of the proper lubricant. - Readjust bearings. - Check gears for excessive wear or scoring. Replace as necessary. - Readjust ring gear and pinion backlash and check gears for possible scoring.

CHASSIS

Shock Absorber and Rear Spring Troubleshooting

Front Suspension and Steering Linkage Troubleshooting—Rear Wheel Drive

Suspension and Steering Linkage Troubleshooting—Front Wheel Drive

Tapered Wheel Bearing Troubleshooting

CONSIDER THE FOLLOWING FACTORS WHEN DIAGNOSING BEARING CONDITION:

- 1. GENERAL CONDITION OF ALL PARTS DURING DISASSEMBLY AND INSPECTION.
- 2. CLASSIFY THE FAILURE WITH THE AID OF THE ILLUSTRATIONS.
- 3. DETERMINE THE CAUSE.
- 4. MAKE ALL REPAIRS FOLLOWING RECOMMENDED PROCEDURES.

 GOOD BEARING	 BENT CAGE CAGE DAMAGE DUE TO IMPROPER HANDLING OR TOOL USAGE. REPLACE BEARING.	 BENT CAGE CAGE DAMAGE DUE TO IMPROPER HANDLING OR TOOL USAGE. REPLACE BEARING.
 GALLING METAL SMEARS ON ROLLER ENDS DUE TO OVERHEAT, LUBRICANT FAILURE OR OVERLOAD. REPLACE BEARING – CHECK SEALS AND CHECK FOR PROPER LUBRICATION.	 ABRASIVE STEP WEAR PATTERN ON ROLLER ENDS CAUSED BY FINE ABRASIVES. CLEAN ALL PARTS AND HOUSINGS, CHECK SEALS AND BEARINGS AND REPLACE IF LEAKING, ROUGH OR NOISY.	 ETCHING BEARING SURFACES APPEAR GRAY OR GRAYISH BLACK IN COLOR WITH RELATED ETCHING AWAY OF MATERIAL USUALLY AT ROLLER SPACING. REPLACE BEARINGS – CHECK SEALS AND CHECK FOR PROPER LUBRICATION.
 MISALIGNMENT OUTER RACE MISALIGNMENT DUE TO FOREIGN OBJECT. CLEAN RELATED PARTS AND REPLACE BEARING. MAKE SURE RACES ARE PROPERLY SEATED.	 INDENTATIONS SURFACE DEPRESSIONS ON RACE AND ROLLERS CAUSED BY HARD PARTICLES OF FOREIGN MATERIAL. CLEAN ALL PARTS AND HOUSINGS, CHECK SEALS AND REPLACE BEARINGS IF ROUGH OR NOISY.	 FATIGUE SPALLING FLAKING OF SURFACE METAL RESULTING FROM FATIGUE. REPLACE BEARING – CLEAN ALL RELATED PARTS.

Tapered Wheel Bearing Troubleshooting

  BRINELLING SURFACE INDENTATIONS IN RACEWAY CAUSED BY ROLLERS EITHER UNDER IMPACT LOADING OR VIBRATION WHILE THE BEARING IS NOT ROTATING. REPLACE BEARING IF ROUGH OR NOISY.	  CAGE WEAR WEAR AROUND OUTSIDE DIAMETER OF CAGE AND ROLLER POCKETS CAUSED BY ABRASIVE MATERIAL AND INEFFICIENT LUBRICATION. CHECK SEALS AND REPLACE BEARINGS.	  ABRASIVE ROLLER WEAR PATTERN ON RACES AND ROLLERS CAUSED BY FINE ABRASIVES. CLEAN ALL PARTS AND HOUSINGS, CHECK SEALS AND BEARINGS AND REPLACE IF LEAKING, ROUGH OR NOISY.
  CRACKED INNER RACE RACE CRACKED DUE TO IMPROPER FIT, COCKING, OR POOR BEARING SEATS.	  SMEARS SMEARING OF METAL DUE TO SLIPPAGE, SLIPPAGE CAN BE CAUSED BY POOR FITS, LUBRICATION, OVERHEATING, OVERLOADS OR HANDLING DAMAGE. REPLACE BEARINGS, CLEAN RELATED PARTS AND CHECK FOR PROPER FIT AND LUBRICATION. REPLACE SHAFT IF DAMAGED.	  FRETTAGE CORROSION SET UP BY SMALL RELATIVE MOVEMENT OF PARTS WITH NO LUBRICATION. REPLACE BEARING. CLEAN RELATED PARTS. CHECK SEALS AND CHECK FOR PROPER LUBRICATION.
  HEAT DISCOLORATION HEAT DISCOLORATION CAN RANGE FROM FAINT YELLOW TO DARK BLUE RESULTING FROM OVERLOAD OR INCORRECT LUBRICANT. EXCESSIVE HEAT CAN CAUSE SOFTENING OF RACES OR ROLLERS. TO CHECK FOR LOSS OF TEMPER ON RACES OR ROLLERS A SIMPLE FILE TEST MAY BE MADE. A FILE DRAWN OVER A TEMPERED PART WILL GRAB AND CUT METAL, WHEREAS, A FILE DRAWN OVER A HARD PART WILL GLIDE READILY WITH NO METAL CUTTING. REPLACE BEARINGS IF OVER HEATING DAMAGE IS INDICATED. CHECK SEALS AND OTHER PARTS.	  STAIN DISCOLORATION DISCOLORATION CAN RANGE FROM LIGHT BROWN TO BLACK CAUSED BY INCORRECT LUBRICANT OR MOISTURE. RE-USE BEARINGS IF STAINS CAN BE REMOVED BY LIGHT POLISHING OR IF NO EVIDENCE OF OVERHEATING IS OBSERVED. CHECK SEALS AND RELATED PARTS FOR DAMAGE.	

Manual Steering Troubleshooting

INSPECTION AND ALIGNMENT

Before any steering gear adjustments are made, it is recommended that the front end of the car be raised and a thorough inspection be made for stiffness or lost motion in steering gear, steering linkage and front suspension. Worn or damaged parts should be replaced, since a satisfactory adjustment of the steering gear cannot be obtained if bent or badly worn parts exist.

It is also very important that the steering gear be properly aligned in the car. Misalignment of the gear places a stress on the steering worm shaft, therefore a proper adjustment is impossible. To align the steering gear, loosen the mounting bolts to permit the gear to align itself. Check the steering gear mounting seat, and if there is a gap at any of the mounting bolts, proper alignment may be obtained by placing shims where excessive gap appears. Tighten the steering gear bolts. Alignment of the gear in the car is very important and should be done carefully so that a satisfactory, trouble-free gear adjustment may be obtained.

Condition	Possible Cause	Corrective Action
Hard steering	1. Low or uneven tire pressure. 2. Insufficient lubricant in the steering gear housing or in steering linkage. 3. Steering gear shaft adjusted too tight. 4. Front wheels out of line. 5. Steering column misaligned.	1. Inflate tires to recommended pressures. 2. Lubricate as necessary. 3. Adjust according to instructions. 4. Align the wheels. 5. See the appropriate Car Section for alignment procedures.
Excessive play or looseness in the steering wheel	1. Steering gear shaft adjust too loose or badly worn. 2. Steering linkage loose or worn. 3. Front wheel bearings improperly adjusted. 4. Steering arm loose on steering gear shaft. 5. Steering gear housing attaching bolts loose. 6. Steering arms loose at steering knuckles. 7. Worn ball joints. 8. Worm shaft bearing adjustment too loose.	1. Replace worn parts and adjust according to instructions. 2. Replace worn parts. 3. Adjust according to instructions. 4. Inspect for damage to the gear shaft and steering arm, replace parts as necessary. 5. Tighten attaching bolts to specifications. 6. Tighten according to specifications. 7. Replace the ball joints as necessary. 8. Adjust worm bearing preload according to instructions.

Power Steering Systems Troubleshooting

Condition	Possible Cause	Corrective Action
Hard steering	1. Improper tire pressure. 2. Loose pump drive belt. 3. Low or incorrect fluid. 4. Loose, bent or poorly lubricated front end parts. 5. Improper front end alignment. 6. Bind in steering column or linkage.	1. Inflate tires to recommended pressures. 2. Tighten or replace belt. 3. Refill reservoir with proper fluid; check for leaks; 4. Tighten or replace parts; lubricate at all fittings. 5. Align front end.

Condition	Possible Cause	Correction Action
Hard steering	- Air in hydraulic system. - Low pump output or leaks in system. - Obstruction in lines. - Pump valves sticking or out of adjustment.	- Disassemble and inspect component parts. Repair or replace as necessary. - Bleed system, refill and check for leaks. - Disassemble pump, check for worn or damaged parts. Check for leaks in the system. - Clean or replace lines. - Replace or adjust valves.
Loose steering	- Loose wheel bearings - Faulty shocks. - Worn linkage components. - Loose steering gear mounting or linkage points. - Steering mechanism worn or improperly adjusted. - Valve spool improperly adjusted	- Adjust wheel bearings. - Relace shocks. - Replace worn components. - Tighten mountings or linkage. - Replace and/or adjust mechanism. - Adjust valve spool.
Veer or wander	- Improper tire pressure. - Improper front end alignment. - Dragging brakes. - Bent frame. - Improper rear end alignment. - Faulty shocks or springs. - Loose or bent front end components. - Play in Pitman arm. - Loose wheel bearings. - Binding Pitman arm. - Spool valve sticking or improperly adjusted.	- Inflate tires to recommended pressures. - Align front end. - Inspect, replace and/or adjust brakes. - Straighten frame. - Inspect shocks and control arm torque. Replace and/or adjust as necessary. - Replace as necessary. - Replace as necessary. - Inspect bushings and arm. Replace as necessary. - Adjust to specifications. - Replace arm. - Adjust or replace as necessary.
Wheel oscillation	- Improper tire pressure. - Loose wheel bearings. - Improper front end alignment. - Bent spindle. - Worn, bent or broken front end components. - Tires out of round or out of balance. - Excessive lateral runout in disc brake rotor.	- Inflate tires to recommended pressures. - Adjust to specifications. - Align front end. - Replace spindle. - Inspect, repair or replace as necessary. - Replace or balance tires. - Reface or replace rotor.
Noises	- Loose belts. - Low fluid, air in system. - Foreign matter in system. - Improper lubrication. - Interference or chafing in linkage. - Steering gear mountings loose. - Incorrect adjustment or wear in gear box. - Faulty valves or wear in pump.	- Replace and/or adjust belts. - Refill and check for leaks. - Disassemble and clean system. - Lubricate all fittings. - Disassemble, inspect, replace or adjust components. - Tighten mountings. - Disassemble, inspect, repair, replace and/or adjust parts. - Replace parts as necessary.

How To Read Tire Wear

The way your tires wear is a good indicator of other parts of the suspension. Abnormal wear patterns are often caused by the need for simple tire maintenance, or for front end alignment.

Over-inflation

Excessive wear at the center of the tread indicates that the air pressure in the tire is consistently too high. The tire is riding on the center of the tread and wearing it prematurely. Occasionally, this wear pattern can result from outrageously wide tires on narrow rims. The cure for this is to replace either the tires or the wheels.

Under-inflation

This type of wear usually results from consistent under-inflation. When a tire is under-inflated, there is too much contact with the road by the outer treads, which wear prematurely. When this type of wear occurs, and the tire pressure is known to be consistently correct, a bent or worn steering component or the need for wheel alignment could be indicated.

Feathering

Feathering is a condition when the edge of each tread rib develops a slightly rounded edge on one side and a sharp edge on the other. By running your hand over the tire, you can usually feel the sharper edges before you'll be able to see them. The most common causes of feathering are incorrect toe-in setting or deteriorated bushings in the front suspension.

One side wear

When an inner or outer rib wears faster than the rest of the tire, the need for wheel alignment is indicated. There is excessive camber in the front suspension, causing the wheel to lean too much putting excessive load on one side of the tire. Misalignment could also be due to sagging springs, worn ball joints, or worn control arm bushings. Be sure the vehicle is loaded the way it's normally driven when you have the wheels aligned.

Cupping

Cups or scalloped dips appearing around the edge of the tread almost always indicate worn (sometimes bent) suspension parts. Adjustment of wheel alignment alone will seldom cure the problem. Any worn component that connects the wheel to the suspension can cause this type of wear. Occasionally, wheels that are out of balance will wear like this, but wheel imbalance usually shows up as bald spots between the outside edges and center of the tread.

Second-rib wear

Second-rib wear is usually found only in radial tires, and appears where the steel belts end in relation to the tread. It can be kept to a minimum by paying careful attention to tire pressure and frequently rotating the tires. This is often considered normal wear but excessive amounts indicate that the tires are too wide for the wheels.

Drum Brake Troubleshooting

Condition	Possible Cause	Correction Action
Pedal goes to floor	1. Fluid low in reservoir. 2. Air in hydraulic brake system. 3. Improperly adjusted brake. 4. Leaking wheel cylinders. 5. Loose or broken brake lines. 6. Leaking or worn master cylinder. 7. Excessively worn brake lining.	1. Fill and bleed master cylinder. 2. Fill and bleed hydraulic brake system. 3. Repair or replace self-adjuster as required. 4. Recondition or replace wheel cylinder and replace both brake shoes. 5. Tighten all brake fittings or replace brake line. 6. Recondition or replace master cylinder and bleed hydraulic system. 7. Reline and adjust brakes.
Spongy brake pedal	1. Air in hydraulic system. 2. Improper brake fluid (low boiling point). 3. Excessively worn or cracked brake drums. 4. Broken pedal pivot bushing.	1. Fill master cylinder and bleed hydraulic system. 2. Drain, flush and refill with brake fluid. 3. Replace all faulty brake drums. 4. Replace nylon pivot bushing.
Brakes pulling	1. Contaminated lining. 2. Front end out of alignment. 3. Incorrect brake adjustment. 4. Unmatched brake lining. 5. Brake drums out of round. 6. Brake shoes distorted. 7. Restricted brake hose or line. 8. Broken rear spring.	1. Replace contaminated brake lining. 2. Align front end. 3. Adjust brakes and check fluid. 4. Match primary, secondary with same type of lining on all wheels. 5. Grind or replace brake drums. 6. Replace faulty brake shoes. 7. Replace plugged hose or brake line. 8. Replace broken spring.
Squealing brakes	1. Glazed brake lining. 2. Saturated brake lining. 3. Weak or broken brake shoe retaining spring. 4. Broken or weak brake shoe return spring. 5. Incorrect brake lining. 6. Distorted brake shoes. 7. Bent support plate. 8. Dust in brakes or scored brake drums.	1. Cam grind or replace brake lining. 2. Replace saturated lining. 3. Replace retaining spring. 4. Replace return spring. 5. Install matched brake lining. 6. Replace brake shoes. 7. Replace support plate. 8. Blow out brake assembly with compressed air and grind brake drums.
Chirping brakes	1. Out of round drum or eccentric axle flange pilot.	1. Repair as necessary, and lubricate support plate contact areas (6 places).
Dragging brakes	1. Incorrect wheel or parking brake adjustment. 2. Parking brakes engaged. 3. Weak or broken brake shoe return spring. 4. Brake pedal binding. 5. Master cylinder cup sticking. 6. Obstructed master cylinder relief port. 7. Saturated brake lining. 8. Bent or out of round brake drum.	1. Adjust brake and check fluid. 2. Release parking brakes. 3. Replace brake shoe return spring. 4. Free up and lubricate brake pedal and linkage. 5. Recondition master cylinder. 6. Use compressed air and blow out relief port. 7. Replace brake lining. 8. Grind or replace faulty brake drum.

26 TROUBLESHOOTING

Condition	Possible Cause	Corrective Action
Hard pedal	1. Brake booster inoperative. 2. Incorrect brake lining. 3. Restricted brake line or hose. 4. Frozen brake pedal linkage.	1. Replace brake booster. 2. Install matched brake lining. 3. Clean out or replace brake line or hose. 4. Free up and lubricate brake linkage.
Wheel locks	1. Contaminated brake lining. 2. Loose or torn brake lining. 3. Wheel cylinder cups sticking. 4. Incorrect wheel bearing adjustment.	1. Reline both front or rear of all four brakes. 2. Replace brake lining. 3. Recondition or replace wheel cylinder. 4. Clean, pack and adjust wheel bearings.
Brakes fade (high speed)	1. Incorrect lining. 2. Overheated brake drums. 3. Incorrect brake fluid (low boiling temperature) 4. Saturated brake lining.	1. Replace lining. 2. Inspect for dragging brakes. 3. Drain, flush, refill and bleed hydraulic brake system. 4. Reline both front or rear or all four brakes.
Pedal pulsates	1. Bent or out of round brake drum.	1. Grind or replace brake drums.
Brake chatter and shoe knock	1. Out of round brake drum. 2. Loose support plate. 3. Bent support plate. 4. Distorted brake shoes. 5. Machine grooves in contact face of brake drum. (Shoe Knock). 6. Contaminated brake lining.	1. Grind or replace brake drums. 2. Tighten support plate bolts to proper specifications. 3. Replace support plate. 4. Replace brake shoes. 5. Grind or replace brake drum. 6. Replace either front or rear or all four linings.
Brakes do not self adjust	1. Adjuster screw frozen in thread. 2. Adjuster screw corroded at thrust washer. 3. Adjuster level does not engage star wheel. 4. Adjuster installed on wrong wheel.	1. Clean and free-up all thread areas. 2. Clean threads and replace thrust washer if necessary. 3. Repair, free up or replace adjusters as required. 4. Install correct adjuster parts.

Disc Brake Troubleshooting

Condition	Possible Cause	Correction Action
Noise—Groan—Brake noise emanating when slowly releasing brakes (creep-groan).	1. Not detrimental to function of disc brakes—no corrective action required. (Indicate to operator this noise may be eliminated by slightly increasing or decreasing brake pedal efforts.)	
Rattle—Brake noise or rattle emanating at low speeds on rough roads, (front wheels only).	1. Shoe anti-rattle spring missing or not properly positioned. 2. Excessive clearance between shoe and caliper.	1. Install new anti-rattle spring or position properly. 2. Install new shoe and lining assemblies.

Condition	Possible Cause	Corrective Action
Scraping	1. Mounting bolts too long. 2. Loose wheel bearings.	1. Install mounting bolts of correct length. 2. Readjust wheel bearings to correct specifications.
Front brakes heat up during driving and fail to release	1. Operator riding brake pedal. 2. Stop light switch improperly adjusted. 3. Sticking pedal linkage. 4. Frozen or seized piston. 5. Residual pressure valve in master cylinder. 6. Power brake malfunction.	1. Instruct owner how to drive with disc brakes. 2. Adjust stop light to allow full return of pedal. 3. Free up sticking pedal linkage. 4. Disassemble caliper and free up piston. 5. Remove valve. 6. Replace.
Leaky wheel cylinder	1. Damaged or worn caliper piston seal. 2. Scores or corrosion on surface of cylinder bore.	1. Disassemble caliper and install new seal. 2. Disassemble caliper and hone cylinder bore. Install new seal.
Grabbing or uneven brake action	1. Causes listed under "Pull." 2. Power brake malfunction.	1. Corrections listed under "Pull". 2. Replace.
Brake pedal can be depressed without braking effect	1. Air in hydraulic system or improper bleeding procedure. 2. Leak past primary cup in master cylinder. 3. Leak in system. 4. Rear brakes out of adjustment. 5. Bleeder screw open.	1. Bleed system. 2. Recondition master cylinder. 3. Check for leak and repair as required. 4. Adjust rear brakes. 5. Close bleeder screw and bleed entire system.
Excessive pedal travel	1. Air, leak, or insufficient fluid in system or caliper. 2. Warped or excessively tapered shoe and lining assembly. 3. Excessive disc runout. 4. Rear brake adjustment required. 5. Loose wheel bearing adjustment. 6. Damaged caliper piston seal. 7. Improper brake fluid (boil). 8. Power brake malfunction.	1. Check system for leaks and bleed. 2. Install new shoe and linings. 3. Check disc for runout with dial indicator. Install new or refinished disc. 4. Check and adjust rear brakes. 5. Readjust wheel bearing to specified torque. 6. Install new piston seal. 7. Drain and install correct fluid. 8. Replace.
Brake roughness or chatter (pedal pumping)	1. Excessive thickness variation of braking disc. 2. Excessive lateral runout of braking disc. 3. Rear brake drums out-of-round. 4. Excessive front bearing clearance.	1. Check disc for thickness variation using a micrometer. 2. Check disc for lateral runout with dial indicator. Install new or refinished disc. 3. Reface rear drums and check for out-of-round. 4. Readjust wheel bearings to specified torque.
Excessive pedal effort	1. Brake fluid, oil or grease on linings. 2. Incorrect lining. 3. Frozen or seized pistons. 4. Power brake malfunction.	1. Install new shoe linings as required. 2. Remove lining and install correct lining. 3. Disassemble caliper and free up pistons. 4. Replace.

26 TROUBLESHOOTING

Condition	Possible Cause	Corrective Action
Pull	1. Brake fluid, oil or grease on linings. 2. Unmatched linings. 3. Distorted brake shoes. 4. Frozen or seized pistons. 5. Incorrect tire pressure. 6. Front end out of alignment. 7. Broken rear spring. 8. Rear brake pistons sticking. 9. Restricted hose or line. 10. Caliper not in proper alignment to braking disc.	1. Install new shoe and linings. 2. Install correct lining. 3. Install new brake shoes. 4. Disassemble caliper and free up pistons. 5. Inflate tires to recommended pressures. 6. Align front end and check. 7. Install new rear spring. 8. Free up rear brake pistons. 9. Check hoses and lines and correct as necessary. 10. Remove caliper and reinstall. Check alignment.

SI METRIC TABLES

The following tables are given in SI (International System) metric units. SI units replace both customary (English) and the older gravimetric units. The use of SI units as a new worldwide standard was set by the International Committee of Weights and Measures in 1960. SI has since been adopted by most countries as their national standard.

To measure:	Use SI units:
mass	kilograms (kg)
temperature	Celsius ($^{\circ}\text{C}$)
length	millimeters (mm)
force	newtons (N)
capacities	liters (l)
torque	newton-meters (N-m)
pressure	kilopascals (kPa)
volume	cubic centimeters (cm ³)
power	kilowatts (kW)

If you have had any prior experience with the metric system, you may have noticed units in this chart which are not familiar to you. This is because, in some cases, SI units differ from the older gravimetric units which they replace. For example, newtons (N) replace kilograms (kg) as a force unit, kilopascals (kPa) replace atmos-

These tables are general conversion tables which will allow you to convert customary units, which appear in the text, into SI units.

The following are a list of SI units and the customary units, used in this book, which they replace:

Which replace (customary units):
pounds (lbs)
Fahrenheit ($^{\circ}\text{F}$)
inches (in.)
pounds force (lbs)
pints/quarts/gallons (pts/qts/gals)
foot pounds (ft lbs)
pounds per square inch (psi)
cubic inches (cu in.)
horsepower (hp)

pheres or bars as a unit of pressure, and, although the units are the same, the name Celsius replaces centigrade for temperature measurement.

If you are not using the SI tables, have a look at them anyway; you will be seeing a lot more of them in the future.

ENGLISH TO METRIC CONVERSION: MASS (WEIGHT)

Current mass measurement is expressed in pounds and ounces (lbs. & ozs.). The metric unit of mass (or weight) is the kilogram (kg). Even although this table does not show conversion of masses (weights) larger than 15 lbs, it is easy to calculate larger units by following the data immediately below.

To convert ounces (oz.) to grams (g): multiply th number of ozs. by 28
To convert grams (g) to ounces (oz.): multiply the number of grams by .035

To convert pounds (lbs.) to kilograms (kg): multiply the number of lbs. by .45
To convert kilograms (kg) to pounds (lbs.): multiply the number of kilograms by 2.2

lbs	kg	lbs	kg	oz	kg	oz	kg
0.1	0.04	0.9	0.41	0.1	0.003	0.9	0.024
0.2	0.09	1	0.4	0.2	0.005	1	0.03

ENGLISH TO METRIC CONVERSION: TORQUE

Torque is now expressed as either foot-pounds (ft./lbs.) or inch-pounds (in./lbs.). The metric measurement unit for torque is the Newton-meter (Nm). This unit—the Nm—will be used for all SI metric torque references, both the present ft./lbs. and in./lbs.

ft lbs	N-m	ft lbs	N-m	ft lbs	N-m	ft lbs	N-m
0.1	0.1	33	44.7	74	100.3	115	155.9

ENGLISH TO METRIC CONVERSION: FORCE

Force is presently measured in pounds (lbs.). This type of measurement is used to measure spring pressure, specifically how many pounds it takes to compress a spring. Our present force unit (the pound) will be replaced in SI metric measurements by the Newton (N). This term will eventually see use in specifications for electric motor brush spring pressures, valve spring pressures, etc.

To convert pounds (lbs.) to Newton (N): multiply the number of lbs. by 4.45

ENGLISH TO METRIC CONVERSION: LIQUID CAPACITY

Liquid or fluid capacity is presently expressed as pints, quarts or gallons, or a combination of all of these. In the metric system the liter (l) will become the basic unit. Fractions of a liter would be expressed as deciliters, centiliters, or most frequently (and commonly) as milliliters.

To convert pints (pts.) to liters (l): multiply the number of pints by .47

To convert liters (l) to pints (pts.): multiply the number of liters by 2.1

To convert quarts (qts.) to liters (l): multiply the number of quarts by .95

To convert liters (l) to quarts (qts.): multiply the number of liters by 1.06

To convert gallons (gals.) to liters (l): multiply the number of gallons by 3.8

To convert liters (l) to gallons (gals.): multiply the number of liters by .26

ENGLISH TO METRIC CONVERSION: PRESSURE

The basic unit of pressure measurement used today is expressed as pounds per square inch (psi). The metric unit for psi will be the kilopascal (kPa). This will apply to either fluid pressure or air pressure, and will be frequently seen in tire pressure readings, oil pressure specifications, fuel pump pressure, etc.

To convert pounds per square inch (psi) to kilopascals (kPa): multiply the number of psi by 6.89

CHILTON'S

TRUCK and VAN

REPAIR MANUAL

1986-90

This is the complete authoritative reference manual for the do-it-yourselfer who services a pick-up, van, recreational or 4-wheel drive vehicle.

Every mass-produced American or import truck is broken down into its component parts—engine, brakes, drivetrain, suspension, etc.—by make, model and year, allowing you to pinpoint problems and make repairs with a minimum of expense and time.

Thousands of clear illustrations take the guess work out of replacing or overhauling components. Time saver tips, specifications, cautions and mechanics' notes from practical experience combine to make any job as easy as possible.

This is the only manual devoted exclusively to domestic and import trucks. Everything the do-it-yourself or experienced mechanic needs is here in two practical sections.

UNIT REPAIR SECTIONS

Tools, equipment and maintenance

Emission controls maintenance

Gasoline and diesel engine rebuilding

Brakes

Charging and starting system service—
alternators, regulators and starters

Engine electronics

Diagnosis and troubleshooting

Carburetor identification, adjustment
and specifications

Drive axle and U-Joints/CV-Joints
service

DOMESTIC AND IMPORT TRUCKS, VANS AND RV'S

- Year, model, engine, and transmission identification
- Specifications for tune-up, fluid capacities, and wheel alignment
- Complete engine service specifications, including valve, ring, bearing and torque specifications and sequences
- Tune-up, component replacement and adjustment for virtually any major component
